19 **Summary:**

20 This study describes a new biopsy method to acquire zebrafish lymphocytes for *ex vivo*
21 studies, without euthanasia. Expression profiles of individual lymphocytes from multiple
22 zebrafish transgenic lines reveal diverse lymphocyte populations, including novel cells
23 expressing genes of both the B- and T-lineages.

Abstract:

Zebrafish are a compelling model to study lymphocytes because zebrafish and humans have similar adaptive immune systems. Human and zebrafish lymphocyte types are conserved, but many aspects of zebrafish lymphocyte biology remain uninvestigated, including lymphocytes in peripheral tissues, like epidermis. Here, we report the first study focused on zebrafish scale epidermal lymphocytes. Zebrafish scales represent a source to longitudinally sample live fish. We developed a novel biopsy technique, collecting scales to analyze epithelial lymphocytes from several fluorescently-labeled lines. We imaged scales via confocal microscopy and demonstrated multiple lymphocyte types in scales/epidermis, quantifying them flow cytometrically. We profiled gene expression of scale, thymic, and marrow lymphocytes from the same animals, revealing B- and T-lineage signatures. Single-cell qRT-PCR and RNA sequencing (scRNAseq) show not only canonical B and T cells, but also novel lymphocyte populations not described previously. To validate longitudinal scale biopsies, we serially sampled scales from fish treated with dexamethasone (DXM), demonstrating epidermal lymphocyte responses. To analyze cells functionally, we employed a bead-ingestion assay, showing thymic, marrow, and epidermal lymphocytes have phagocytic activity. In summary, we establish a non-lethal technique to obtain zebrafish lymphocytes, providing the first quantification, expression profiling, and functional data from epidermal lymphocytes in the zebrafish model.

Introduction:

Immune cell functions are well-established in skin,¹⁻⁵ which serves as both a barrier and a lymphoid organ.^{1,3} Mammalian cutaneous lymphocytes include epidermal cytotoxic T (CTL) and dermal B, T, and natural killer (NK) cells.⁶⁻⁹ Zebrafish share B/T/NK lymphocytes, surface immunoglobulin (slg), T cell receptors (TCR), MHC molecules, and other immunologic features with mammals.¹⁰⁻¹² Zebrafish lymphocytes are well-characterized,¹³⁻²⁰ but most studies focus only on cells of lymphoid tissues. Several reports briefly mention epidermal lymphocytes: one noted *igm*⁺ skin B cells;¹⁹ another *mpeg1.1*⁺ B cells;¹⁴ a third identified B-1-like cells in multiple organs, including skin.²¹ However, these reports concentrate on thymus, marrow, and spleen, while most skin/scale studies investigate osteogenesis^{22,23} or melanoma.²⁴

Zebrafish are small, making non-lethal lymphocyte collection difficult. Obtaining blood retro-orbitally²⁵ is technically-challenging, with serial-sampling infeasible. Instead, most reports (including ours^{18,26,27}) collect lymphocytes post-euthanasia, precluding longitudinal studies. Here, we describe a new method to collect 1-20 scales/fish, yielding hundreds-to-thousands of lymphocytes and permitting repeated sampling. Via scale biopsy, we examined several transgenic lines, identifying, quantifying, and expression-profiling epidermal lymphocytes. Single-cell studies revealed B- and T-lineage subtypes and potentially novel lymphocyte populations. We also functionally tested lymphocyte DXM-responses and phagocytosis. Overall, we describe a simple technique to collect zebrafish epidermal lymphocytes and their first comprehensive study.

Materials & Methods:

Zebrafish

Zebrafish care was reported previously,^{18,26,27} with a 14:10-hour circadian-cycled colony kept at 28.5°C. Experiments followed IACUC-approved protocols. Anesthesia utilized 0.02% tricaine methanesulfonate (MS-222). Transgenic *cd79:GFP*¹⁵ and *lck:mCherry* fish (from the Zon laboratory, Harvard University) were inter-bred, creating double-transgenics.

Biopsies

Scale biopsy is detailed in Supplemental Materials.

Microscopy

Anesthetized 3-to-9m fish were imaged with a Nikon AZ100 microscope. Low- and high-exposure images were obtained as previously^{18,26} using a Nikon DS-Qi1MC camera and NIS Elements (V4.13) software. Select images are brightened to enhance dim-fluorescence.

Confocal imaging

Scales were slide-mounted with SlowFade™ Glass Soft-set Antifade Mountant plus DAPI. Imaging utilized a Leica-SP8 confocal microscope and LAS-X (V3.7.4.23463) software.

Flow cytometry/FACS

Tissues were pestle-dissociated and passed through 35µm filters.²⁶ Cells were collected from lymphoid/precursor gates using a BD-FACSJazz (Becton-Dickinson). Flow cytometry used a CytoFLEX™ and Kaluza software (Beckman-Coulter).

qRT-PCR

RNA was extracted using Trizol (Invitrogen). Total RNA triplicates (16ng) were reverse-transcribed for SYBR-Green qRT-PCR with a CFX96 Touch™-PCR System (Biorad). Two^{-ΔCt} (Ct_Δ = Ct_{experimental} - Ct_{housekeeping})²⁸ calculated expression relative to *β-actin* and *eef1a1l1*.

Single-cell qRT-PCR

Cells were FAC-sorted into 96-well plates, lysed, and cDNA synthesized using Fluidigm™ protocols. Supplementary Material lists sc-qRT-PCR details. CT values were converted to Log2Ex using a limit of detection (LoD) = 27. Other LoDs yielded similar results. Cells expressing >30% T- and <30% B-lineage genes were designated T-lineage, and vice versa. Cells expressing >30% of T- and B-lineage genes were designated Bi-Phenotypic.

scRNAseq

Cell-capture utilized 10xGenomics Chromium, with Illumina NovaSeq6000 sequencing. Cells (18,000 thymic; 8,800 marrow; 3,500 scale) were loaded (1,000 cells/μl) on 10xGenomics single-cell v2 chips into a Chromium controller and processed per 10xGenomics protocol. Supplementary Material details data-processing and analysis steps.

DXM treatment

Zebrafish were continuously-housed for 10d in 10μg/ml DXM in 500ml fish water, changed daily, as previously.²⁷ Fish were imaged pre- and post-treatment, with fluorescence-integrated densities quantified via ImageJ.²⁹

Phagocytosis assays

Fluorescent lymphocytes were sorted into 1.5ml Eppendorfs in 5μl volumes with a BD-FACSAria Fusion (Becton-Dickinson), incubated with 1μl of 1:1000-diluted 1μm blue-

104 FluoSpheres (Thermo-Fisher) for 30min, and analyzed via ImageStream™ MkII and IDEAS
 105 software (Luminex).

106 **Data Sharing Statement**

107 scRNA-seq data used in this study are available at GEO under accession number
 108 GSE237417.

Results:

Zebrafish epidermal lymphocytes

To investigate zebrafish epidermal lymphocytes, we analyzed transgenic fish bearing lymphocyte-specific fluorophores. Microscopy of B-labeled lines, *cd79a:GFP* and *cd79b:GFP*,¹⁵ exhibited head and gill fluorescence; T cell-specific *lck:GFP* fish displayed thymic fluorescence (Figure 1A), as previously described.^{13,26,27} To determine whether fluorescence emanated from skin/scales, we developed a novel scale biopsy method (details in Supplemental Material).

Upon removal, epidermis remains attached to lateral/exterior and medial/interior scale surfaces (Figure 1B, DAPI).²² Expectedly, by fluorescent microscopy, wild-type (WT) scales lacked fluorescence (Figure 1B, left) except rare auto-fluorescent cells (Figure S1A). However, *cd79a:GFP*, *cd79b:GFP*, and *lck:GFP* epidermis (Figure 1B, right three columns) were all fluorescent. Confocal imaging revealed GFP⁺, ~10µm lymphocytes, some with cytoplasmic protrusions (Figures 1B red-boxes, S1A yellow-boxes), confirming these findings. 3-Dimensional confocal microscopy movies of scales display fluorescent cells from various perspectives (Figure S1B).

Identifying epidermal lymphocytes

We next analyzed fluorescent cells from scales of these and two additional transgenic lines: dual-transgenic *lck:GFP;rag2:hMYC* fish have lymphocytosis and eventually develop acute lymphoblastic leukemias;^{18,26,27} we also tested *lck:mCherry* fish (gift from the Zon laboratory, Harvard University). We identified lymphoid gates³⁰ by forward- and side-scatter (Figure 2A) and detected fluorescent epidermal cells from each line (Figure 2B). B-labeled lines (*cd79a:GFP*, *cd79b:GFP*) exhibited GFP^{lo} and GFP^{hi} populations, (Figure 2B, upper-histograms). T-labeled

lck:GFP (+/- *rag2:hMYC*) and *lck:mCherry* scales had only GFP^{lo}/mCherry^{lo} cells (Figure 2B, lower-histograms). Transgenic human *MYC* (*hMYC*) did not alter GFP intensity, but slightly increased GFP^{lo} cells/scale (quantified subsequently).

To confirm cell identities, we measured B- (*pax5*, *cd79b*, *ighm*, *ighz*), T- (*cd4*, *cd8*, *lck*), and lymphoblast- (*igic1s1*, *rag2*) transcripts by qRT-PCR (primers in Supplementary Table 1). GFP⁺ cells (GFP^{lo} + GFP^{hi}) of both *cd79* lines expressed B-lineage mRNAs, unlike GFP⁺/mCherry⁺ cells of *lck* fish (Figure 2C, top). Thus, both *cd79* lines label the B-lineage, further proving that B cells reside in zebrafish epidermis. Oppositely, *lck* lines' fluorescent cells expressed T-lineage genes, unlike both *cd79* lines (Figure 2C, middle), demonstrating T cells also populate scales. Both *cd4* and *cd8* were detected in *lck:mCherry* scales, indicating both T_H and CTL are present. However, *cd8* was not detected in *lck:GFP* scale cells, suggesting a difference between the *lck* lines. Scale lymphocytes lacked *rag2* (Figure 2C, bottom), implying they are mature B and T cells. However, we detected *igic1s1* (which we previously postulated to be a pre-B surrogate Ig light chain³¹) in epidermal B cells of both *cd79* lines. This may reflect residual mRNA in mature B cells, or that our prediction is erroneous. Regardless, these data demonstrate T_H, CTL, and B cells each reside in zebrafish epidermis.

Single-cell profiles reveal multiple epidermal lymphocyte types

We next analyzed GFP^{hi} and GFP^{lo} cells from *cd79a* and *cd79b* scales, thymus, and marrow of the same fish via single-cell multiplex-qPCR, using orthologues that distinguish B, T, and other mammalian leukocytes (Figure 3A).^{26,27,32} We tested 16 B- (*pax5*, *cd79a*, etc.) and 10 T-lineage (*cd4*, *lat*, etc.) transcripts, 17 lymphoblast (*rag1*, *rag2*), leukocyte (*l-plastin*), erythroid

(*ba1*), or lymphocyte (*bcl6a*, *id3*, *ets1*) mRNAs, plus housekeeping (*eef1a1l1/ef1a*) and control (*GFP*) genes (primers in Supplementary Table 2).

GFP^{hi} thymocytes of *cd79a* fish expressed B-lineage genes (*pax5*, *cd79a*, *cd79b*, *ighm*, etc.), supporting bulk qRT-PCR results, and other B cell receptor (BCR)-related genes *syk*, *lyn*, and *blnk*, but not T-lineage genes. Cells lacked *rag1/2*, but 10/22 expressed *il7r*, like pre-B cells.³³ We designated these GFP^{hi} thymocytes “*pax5*⁺ mature B cells” (Figure 3A, 1st-column).

Unexpectedly, *cd79a* GFP^{lo} thymocytes had near-opposite profiles, with mostly T- rather than B-lineage transcripts (Figure 3A, 2nd-column). Thus, unexpectedly, they are T cells. Curiously, although GFP^{lo} in the *cd79a:GFP* background, these cells lacked *cd79a* mRNA and had low-to-undetectable *GFP* transcripts. We postulate these cells transcribed *cd79a* and *GFP* previously, but when FACS-purified, only scant GFP protein remains, explaining their GFP^{lo} status. Notably, human T-lymphoblast cancers are occasionally CD79A⁺,³⁴⁻³⁶ suggesting some T-lymphoblasts may express *CD79A*. Alternatively, *cd79a:GFP* may imperfectly recapitulate genuine *cd79a* expression. Regarding *cd4* and *cd8*, most GFP^{lo} cells were immature *cd4/cd8* double-positive (DP) or mature *cd8* single-positive (SP), with only one *cd4* SP cell (Figure 3B, left).

We simultaneously analyzed scale lymphocytes. Scale GFP^{hi} cells were near-identical to GFP^{hi} B-thymocytes (Figure 3A, 3rd vs. 1st-columns), except ~32% (14/44) had detectable *rag2*, suggesting recent Ig-recombination. Thus, some skin B cells are likely newly-immigrated. Unlike GFP^{lo} thymocytes, which were mostly T-lineage (Figure 3A, 2nd-column), GFP^{lo} scale cells (4th-column) comprised several cell types: 50% (19/38) resembled GFP^{lo} thymocytes, but only SP (*cd4*/T_H or *cd8*/CTL, not DP). Another ~37% (14/38) were highly unusual, with high levels of

both B- (*cd79b*, *lyn*, *blnk*, etc.) and T- (*cd8*, *lck*, *lat*, etc.) lineage mRNAs. We designated these, which express both BCR- and TCR-signaling pathway genes, as “Bi-Phenotypic” (BiP) cells (tan in Figure 3A). Many also expressed *ighm* and/or *ighz*, and *mpeg1.1*, another zebrafish B-lineage marker.¹⁹ However, BiP cells lacked other B-lineage genes (*pax5*, *btik*, *syk*, *cd79a*) that GFP^{hi} scale/thymic B cells expressed, also dissimilar from previously-described BiP-ALL.^{37,38} To further delineate BiP cells, we ranked GFP^{lo} scale cells using T (*cd4/cd8*) versus B (*cd79b*) transcripts (Figure 3B, middle), resulting in ~29% BiP (tan), ~24% T (red), ~16% B (light blue), with ~32% uncategorized (green). Plotting *cd2* vs. *cd79b* yielded similar results (Figure S2A, upper plot). BiP lymphocytes, which have not been reported previously, were also detected in other populations (tan hashes in Figure 3A, 2nd-6th columns, and subsequent figures).

We also analyzed marrow lymphocytes. Like thymus and skin, marrow GFP^{hi} cells were mostly B-lineage (Figure 3A, 5th-column), with little *rag1* (1/22) or *rag2* (5/22), suggesting mature B cells transcribe more *cd79a* (thus, they are GFP^{hi}). Marrow GFP^{lo} cells differed from GFP^{lo} thymic/scale cells. In marrow, few GFP^{lo} lymphocytes (~14%) were T-lineage (Figure 3A, 6th-column); most cells (~81%) resembled other tissues’ GFP^{hi} B cells. Marrow GFP^{lo} vs. GFP^{hi} B cell maturity also differed, with just ~23% of GFP^{hi} B cells *rag1*⁺/*2*⁺ versus ~48% of GFP^{lo} B cells (again showing B-precursors have lower *cd79a* and GFP). A two-gene index (*lat* for T, *pax5* for B) estimated marrow GFP^{lo} cells at 19% T, 67% B, with 3 unclassified cells (Figure 3B, right). Plotting *cd2* vs. *pax5* was identical (Figure S2A, lower dot plot).

In summary, all *cd79a* GFP^{hi} lymphocytes exhibited unambiguous B-lineage profiles, but GFP^{lo} lymphocytes varied by tissue: GFP^{lo} thymocytes were DP or SP (mostly *cd8*⁺/CTL) T cells. Marrow GFP^{lo} cells were ~81% B-lineage (~48% immature *rag*⁺) and ~14% T-lineage. Scale GFP^{lo}

cells were most complex, comprising $cd4^+$ or $cd8^+$ SP T cells and mixed-lineage BiP lymphocytes. Thymus and marrow also contained occasional BiP cells. To independently re-test these findings, we next analyzed *cd79b:GFP* fish.

GFP^{hi} thymocytes of *cd79b* fish resembled *cd79a* thymic $pax5^+$ B cells (1st-columns of Figure 3C vs. 3A), but dissimilarly, ~24% were $rag1^+$ and/or $rag2^+$. Two-gene analysis (*rag2*, *pax5*) delineated these B-subtypes (Figure 3D, left). Unlike *cd79a* GFP^{lo} thymocytes that were T-lineage, *cd79b* GFP^{lo} thymocytes harbored two B-populations: immature ($pax5^-/rag2^+$) and mature ($pax5^+/rag2^-$; Figure 3C, 2nd-column), which were mutually-exclusive by two-gene (*rag2/pax5*) analysis (Figure 3D, right). GFP^{lo} mature- $pax5^+$ cells expressed no *ighz* and much higher *ighm* than GFP^{lo} immature- $pax5^-$ B-thymocytes, which transcribed *ighm* and *ighz* similarly. The immature $pax5^-/rag2^+$ population was clearly B-lineage, highly expressing Ig-variable genes (*igic1s1*, *igiv2s1_2*), and Ig-constant (*ighm*, *ighz*), *cd79b*, *lyn*, *blnk*, and *mpeg1.1* transcripts. However, they also resembled *cd79a* BiP cells that were $pax5^-/cd79a^-$ and expressed *ighm* and/or *ighz* and *cd8*. Finally, like GFP^{hi} B-precursors, they exhibited high *rag2*, *rasa4*, *gata3*, *il7r* and *myc* orthologues. We speculate these cells are nearing B-lineage commitment, silencing non-B genes and initiating Ig-rearrangement.

GFP^{hi} *cd79b* scale cells (Figure 3C, 3rd-column) matched GFP^{hi} *cd79a* scale B cells (Figure 3A, 3rd-column) and GFP^{hi} *cd79b* thymocytes (Figure 3C, 1st-column), but as in *cd79a* fish, GFP^{lo} scale cells (Figure 3C, 4th-column) had multiple populations: (1) mature- $pax5^+$ B cells (identical to thymic GFP^{lo} $pax5^+$ B cells), (2) $pax5^-$ B cells (different from thymic $pax5^-$ B cells, with higher *cd4*, *mpeg1.1*, absent *ba1*, and low-to-absent *ighm*, *ighz*, and other Ig mRNAs), (3) T cells

(resembling *cd79a* GFP^{lo} scale cells), and (4) BiP cells resembling *cd79a* GFP^{lo} scale BiP lymphocytes. A fifth unclassifiable group (~19%) co-expressed low B-/T-lineage gene levels.

Marrow *cd79b* cells confirmed prior results, with >90% GFP^{hi} and >50% GFP^{lo} cells having mature-*pax5*⁺ B-profiles like those seen in thymus/scales (Figure 3C, 5th-6th columns). Remaining GFP^{lo} marrow cells were *pax5*⁻, yet expressed other B-lineage genes. Unlike *cd79a*, no marrow GFP^{lo} cells were T-lineage in *cd79b* fish. Overall, most GFP^{hi} cells (198/214; ~93%) in every tissue from both *cd79*-labeled lines were B-lineage; B-subtypes varied by tissue and genotype. Another ~7% (16/214) showed BiP features. Both lines' GFP^{lo} cells were more complex, containing B, T, and BiP cells; subtypes (e.g., *pax5*⁺ vs. *pax5*⁻) also varied by tissue and genotype. We also analyzed GFP⁻ cells. Many were not convincingly lymphoid, although some GFP⁻ B, T, and BiP cells were detected (Figure S2B).

Single-cell profiling double-transgenic fish

We next bred *cd79a:GFP* to *lck:mCherry* fish to make double-transgenics that resembled both parental lines (compare Figures 4A and 1A). From these, we purified four populations: P1—GFP^{hi}/mCh⁻; P2—GFP^{lo}/mCh^{hi}; P3—GFP⁻/mCh^{hi}; P4—GFP⁻/mCh^{lo}; abundance varied by tissue (Figure 4A, Table 1). sc-qPCR revealed multiple profiles (Figure 4B). P1 was exclusively B-lineage in every tissue. P2 resembled *cd79a* GFP^{lo} thymocytes, with two differences: (1) DP cells were absent (versus 23% of *cd79a* GFP^{lo} thymocytes; Figure 3B vs. S3A) with most being SP *cd8*⁺/CTL. (2) Few P2 cells were *gata3*⁺, versus 68% of *cd79a* GFP^{lo} thymocytes. Mammalian T_H2, invariant NK/T2 (iNKT2), and innate lymphoid cell-2 (ILC2) cells express GATA3, perhaps explaining this.^{39,40}

GFP⁻ thymocytes that differed by mCherry level (P3, mCh^{hi}; P4, mCh^{lo}) were both primarily T-lineage, resembling P2. Many P2-P4 thymocytes also expressed B-lineage transcripts (*cd79b*, *syk*, *lyn*, *blnk*), like BiP cells (Figure 4B, thymus P2-P4 columns. Scale and marrow P2-P4 mimicked thymic P2-P4, with many cells also having BiP-profiles (Figure 4B, scale/marrow P2-P4 columns).

We also analyzed *lck:GFP* fish, whose thymic fluorescence resembled *lck:mCherry* (Figure 4A, 4C). Thymi had large GFP^{hi} and smaller GFP^{lo} fractions, but unlike mCherry scales/marrow that contained both mCh^{hi} and mCh^{lo} cells (Figure 4A), *lck:GFP* scales/marrow contained no GFP^{hi} cells (Figure 4C). By sc-qPCR, *lck:GFP* GFP^{lo} thymocytes had strong T-signatures, like P4 (mCh^{lo}) thymocytes (Figure 4D 1st-column vs. 4B 4th-column). However, ~80% were *rag1*^{+/2+}, versus no thymic P4 cells. These *rag*⁺ cells had BiP features, expressing Ig (*igic1s1*, *igiv2s1_2*, *ighm*, *ighz*), BCR (*cd79b*, *syk*, *lyn*, *blnk*), and other B-lineage genes (e.g., *mpeg1.1*; Figure 4D), but none expressed *cd4* and only ~14% *cd8*, implying GFP^{lo} thymocytes are T-progenitors just initiating TCR recombination. Conversely, most GFP^{hi} thymocytes expressed *cd8* and/or *cd4* (~44% DP, ~41% *cd8*⁺SP, ~6% *cd4*⁺SP; Figure S3B), *rag1/2*, and other T-genes; 30% showed BiP features (Figure 4D, 2nd-column). We anticipated scale GFP^{lo} cells would resemble P4. Instead, they exhibited three profiles: 38% were GFP^{lo} thymic BiP cells, 50% T-lineage (like P4), and 12% B-lineage (Figure 4D, 3rd-column). Marrow GFP^{lo} cells were similar (45% BiP, 42% T, 10% B; Figure 4D, 4th-column).

Comparing both lines, we draw five conclusions: (1) P1 is B-lineage. (2) P2-P4 are largely T-lineage, with P2 (mCh^{hi}), P3 (also mCh^{hi}), and P4 (mCherry^{lo}) all containing BiP lymphocytes. (3) Surprisingly, T-lineage cells are more uniform in dual-transgenic (mCh^{lo} and mCh^{hi} cells in every

tissue) than *lck:GFP* (GFP^{hi} cells only in thymus). Cell profiles in *lck:GFP* also varied more. (4)
Like preceding genotypes, B and T lymphocytes are abundant in epidermis. (5) Reproducibly,
BiP cells are found in every tissue and genotype.

Epidermal lymphocyte quantification

Defining cell subtypes and frequencies allowed lymphocyte quantification post-biopsy,
via extrapolated identities from gene expression profiles (GEP; Figures 3-4). *cd79a:GFP* scales
had ~40 GFP^{hi} (84% B-lineage, 16% BiP; Figure 3A) and ~58 GFP^{lo} (50% T, 37% BiP, 8% B)
cells/scale (Figure 5A, Table 2). *cd79b:GFP* scales had ~6 GFP^{hi} (100% B; Figure 3C) and ~29
GFP^{lo} (50% B, 22% T, 9% BiP) cells/scale. We also tested *IgM1:GFP* (which labels *ighm*⁺ B cells)
scales,¹⁴ finding ~10 GFP⁺ B cells/scale, less than *cd79* fish, where both Ig-lineages express GFP.

lck:GFP scales (Figure 5B, Table 2) had no GFP^{hi} and ~63 GFP^{lo} cells/scale (50% T, 38% BiP,
12% B; Figure 4D). We also analyzed *lck:GFP* in *casper* (lacking melanophores and iridophores⁴¹)
and *hMYC* backgrounds. *Casper* scales had no GFP^{hi} and ~58 GFP^{lo} cells/scale, comparable to
WIK lck:GFP. *hMYC* scales resembled *WIK lck:GFP*, with no GFP^{hi} and ~95 GFP^{lo} cells/scale (43%
T, 32% BiP, 15%B; Figure S3C). A *rag2* promoter drives *hMYC*, and ultimately induces ALL.^{26,27,42}
Scales of this genotype had more lymphocytes, but we excluded fish with ALL, and the ~50%
increase (95 vs. 63) was statistically insignificant. Excluding *hMYC* fish, we recovered an average
of ~64 lymphocytes/scale from the *cd79* and *lck* genotypes analyzed (Table 2).

Lymphocyte scRNAseq

We next performed scRNAseq on GFP^{hi} thymocytes and GFP^{lo} scale/marrow cells from
lck:GFP fish. After QC, we obtained 1,890 cell GEPs, which clustered into 13 populations (0-12;
Figure 6A; analysis details in Supplemental Material). To identify groups, we examined T-/B-

/NK-lineage defining genes,^{26,43-45} plus our sc-qPCR data (Supplementary Table 2 genelist). We also examined ILC-genes, but found little expression. UMAP demonstrated the lower cluster group (Populations 3, 5, 6, 8, and 10) was near-exclusive to thymus (Figures S4C-D), suggesting these are immature T cells. Only Population 12 in this lower group (black in Figures 6A, S4A) contained appreciable non-thymocytes, with >1/3 marrow-derived (Figure S4C-D). Relative enrichment scores were to build violin plots, showing Population 3 with the strongest T-lineage profile (dark-green in Figure 6A). Like Population 3, other thymus-derived clusters (Populations 5, 6, 8, 10) had high *rag1/2*, *lck*, *GFP*, and other T-lineage transcripts (Figure S4B). Populations 3, 5, 6, and 8 contained *cd4*⁺/*8*⁺ DP cells, while Population 10 was DN *rag1/gata3*⁺. Only Population 8 had little *il7r*. Mammalian DN4 and DP T-lymphoblasts down-regulate *IL7R*, arguing thymic-derived Populations 3, 5, 6, and 10 are likely immature T cells of these stages, with Population 8 being an earlier developmental stage.⁴⁶ A key feature differentiating Populations 5, 6, and 8 was cell-cycle stage: Population 8 was near-entirely S-phase, Population 5 was G₂/M, and Population 6 contained G₀/G₁, S, and G₂/M cells.

Population 12 (black cluster in Figure 6A) showed a violin plot B-signature, was *cd4/8/rag*⁻, and from only thymus and marrow (Figures S4C-D). Population 12 cells also expressed myeloid markers like *spi1b*, *cepba*, and *fcer1g* (Supplemental Table 3). Comparison to human genesets by over-representation analysis (details in Supplemental Material) corroborated this, suggesting Population 12 contains primarily myeloid/dendritic cells.

Most upper UMAP clusters (Populations 0, 1, 2, 4, 7, 9; Figure 6A) were seen in all three tissue types, including scales (Figure S4C-D), with only Population 11 absent in scales. Populations 0 and 1 (light- and dark-blue) had violin plot T-lineage signatures and were either

cd4⁺SP (the majority) or *cd8*⁺SP (the minority; Figure S4B). Population 7 (dark-orange) likewise contained *rag*⁻ mature *cd4*⁺ SP or *cd8*⁺ SP T cells. Populations 2 and 4 (light-green and pink, Figure 6A) were large clusters in the upper UMAP group, most abundant in scales (Figure S4C). Their violin plots indicated B-signatures (Figures 6A, S4D), but many B-specific markers (i.e., *cd79*) were not detected by scRNAseq, except *syk* (both populations) and *lyn* (primarily Population 4; Figure S4B). Much of Population 4 expressed *nkl.2* (a human *GNLY* orthologue; Figure S4B) suggesting it may contain NK cells. Violin plots for Population 4 support this. Over-representation analysis of Population 2 and 4 markers and human genesets indicate both contain NK cells, with Population 2 cells being *id3*⁺.

As noted, Population 11 (brown, Figure 6A) was absent in scales (Figure S4C) and rare overall. Some cells were faintly *cd4*⁺/*8*⁺ DP, but violin plots were inconclusive. Cluster-specific markers *egr2b*, *cebpd*, and *lcp2a*, and high *cd63* levels indicate Population 11 likely includes granulocytes (Supplemental Table 3), which over-representation analysis with human genesets corroborated. Finally, Population 9 cells (purple, Figure 6A) were rare and nearly scale-exclusive (Figure S4C). They were *cd4*⁻/*8*⁻ and *rag1*⁻/*2*⁻, with high *syk* and *il7r* (Figure S4B). Over-representation analysis indicated Population 9 correlated with NK/NKT cells, and this cluster had many differentially-expressed NK-lineage genes (*sla2*, *cebpb*, *socs1a*, etc.; Supplemental Table 3). Population 9 resembles Populations 2 and 4, with higher *il7r* being a key difference (Figure S4B).

Lymphocyte DXM-sensitivity

To functionally test epidermal lymphocytes, we used DXM,²⁷ which depletes mammalian lymphocytes.^{47,48} We serially-biopsied fish pre-/post-10d of treatment, analyzing by microscopy

and FACS. To exclude potential biopsy-induced inflammatory effects, we alternated flanks for pre-/post-treatment sampling and also serially-biopsied untreated fish.

Following DXM, microscopic fluorescence declined ~50% in *cd79a* and *cd79b* fish (Figure 7A-B, upper-rows), with ~85% fewer GFP^{hi}/GFP^{lo} scale cells by FACS (Figures 7A-B, lower-rows). *lck:GFP* fish exhibited ~20% fainter thymic fluorescence and ~70% fewer scale GFP^{lo} cells (Figure 7C). *lck:mCherry* and double-transgenic (*cd79a:GFP/cd79b:GFP* + *lck:mCherry*) fish yielded similar results (Figure 7D-F). Untreated controls had non-significant differences in all parameters (Figure S5A-S5C). We conclude DXM depletes zebrafish epidermal lymphocytes, as in mammals.^{47,48}

Lymphocyte phagocytosis

Zebrafish *mpeg1.1*⁺ B cells are phagocytic,^{19,21} and many cells were *mpeg1.1*⁺ (Figures 3-4), so we performed bead-ingestion assays (Figure 8A-C).¹⁹ *cd79a* GFP^{lo} marrow (81% B; ~38% *mpeg1.1*⁺; Figure 3A) and *cd79b* GFP^{hi} thymic/scale (93-100% B, >84% *mpeg1.1*⁺; Figure 3C) cells had substantial (22-35%) phagocytosis. In *lck:GFP* fish, GFP^{lo} cells from every tissue and GFP^{hi} thymocytes were highly phagocytic also (26-32% and 59%, respectively). To compare cell types, we categorized groups as B, T, or mixed (B, T, and/or BiP cells) based on prior sc-qPCR. While every category showed phagocytic activity, we saw no significant differences (Figure 8C). Thus, many zebrafish lymphocytes—including those in epidermis—are phagocytic.

Discussion:

Unlike zebrafish, mammalian epidermal lymphocytes are well-described.¹⁻⁵ Studies in fish have discovered new molecules and cell types,^{21,49-51} and can also inform cutaneous immunity. Here, we provide the first thorough description of zebrafish epidermal lymphocytes. Imaging transgenic fish scales identified epidermal fluorescent cells (Figures 1B, S1B). FACS corroborated this, with GFP^{hi}/GFP^{lo} cells in *cd79:GFP* scales and GFP^{lo} cells in *lck:GFP* scales (Figure 2B). qRT-PCR showed GFP⁺ cells in *cd79* lines are B-lineage and GFP^{lo}/mCherry^{lo} cells in *lck:fluorophore* fish are T-lineage (Figure 2C).

Single-cell qRT-PCR of lymphocytes from *cd79a* tissues revealed heterogeneity, with most GFP^{hi} cells B-lineage, but GFP^{lo} profiles varying, especially in scales. BiP cells that express T-/B-lineage transcripts equally were detected in all tissues, being most abundant in epidermis (Figure 3A). Their lower frequency in lymphopoietic organs argues they are not lymphoid precursors, and warrants future investigation of this novel population.

Results in *cd79b* fish further clarified cell identities: First, immature and mature thymic B-populations were each detected (Figure 3C). Second, all tissues contained B-lineage GFP^{lo} cells lacking *pax5*, plus other differences from *pax5*⁺ B cells. Our data expand upon a prior *cd79* study,¹⁵ which noted GFP⁻ *lck*⁺ marrow cells (here, GFP^{lo}), but did not examine them. Thus, the B-fraction schema¹⁵ they proposed omitted populations newly described here. Our discovery of T and BiP cells with low *cd79a/b* levels further expands both lines' utility.

We also examined well-characterized *lck:GFP* fish^{13,16-18,45,52} Previously, we found GFP^{lo} B-ALL in these^{18,26,27} indicating GFP^{lo} cells were B-lineage, but here GFP^{lo} thymocytes had multiple identities, with individual skin/marrow GFP^{lo} cells having T-, BiP-, and B-GEPs (Figure

4D). Thus, *lck* expression, often considered T-specific, actually varies by tissue, and even within tissues.

We also analyzed double-transgenic fish (Figure 4A-B). P1 (GFP^{hi}-only) was uniformly B-lineage and similar across tissues. P2 (GFP^{lo}/mCh^{hi}) was chiefly T-lineage, but also contained BiP cells in each tissue. P3 (GFP⁻/mCh^{hi}) was also primarily T-lineage, but despite no GFP-fluorescence and undetectable *cd79a*, many P3 cells had BiP features, with high *cd79b* and other B-lineage—including *GFP*—transcripts. P4 (GFP⁻/mCh^{lo}) resembled P2 and P3, containing both T and BiP cells, but unlike P2-P3, also harbored rare B cells.

Biopsies yielded ~60 lymphocytes/scale (Figure 5, Table 2). With ~700 scales and rapid regrowth,²² twenty zebrafish scales can provide >10³ lymphocytes. Exploiting this, we piloted scRNAseq using *lck:GFP* scale cells and lymphopoietic controls. GEP revealed 13 clusters (Figure 6A), with Populations 3, 5, 6 and 8 representing *il7r*⁻ DN4/DP T-lymphoblasts, Population 4 exhibiting strong B- and NK-GEP, and Population 2 potentially harboring BiP lymphocytes (Figures 6B, S4B, S4D). Expectedly, scRNAseq of *lck:GFP* lymphocytes fails to answer many questions, as this transgene does not label all lymphocytes, even when parsed into GFP^{lo} and GFP^{hi} fractions. scRNAseq of *cd79a*, *cd79b*, and our novel double-transgenic lines will likely resolve these issues.

Functionally, we tested DXM (which depletes mammalian lymphocytes),^{47,48} quantifying epidermal lymphocyte responses. All genotypes showed diminished fluorescence by microscopy and decreased cell numbers by cytometry (Figure 7). Finally, we also demonstrated phagocytosis by multiple lymphocyte populations (Figure 8).

387 Overall, we describe new methodology to collect fish epidermal lymphocytes, and the
388 first comprehensive description of these cells, advancing zebrafish adaptive immunity modeling.
389 This will facilitate lymphocyte-based investigations, including longitudinal studies where serial-
390 sampling bolsters experimental design.

Acknowledgments:

We thank Aya Ludin and Len Zon (Harvard University) for sharing Tg(*lck:mCherry*) transgenic fish.

Role of Funding Sources:

Studies were supported by grants from the OUHSC Stephenson Cancer Center Pilot Grant Program, the Oklahoma Center for Adult Stem Cell Research, the Presbyterian Health Foundation Team Science and Seed Grant Programs, and the W.J. Jones Family Foundation. Studies by the OUHSC Stephenson Cancer Center Molecular Biology and Cytometry Research Core (confocal microscopy, flow cytometry/FACS, ImageStream™) were supported by NCI Cancer Center Support Grant Award (P30 CA225520).

Authorship Contributions:

GP and JKF conceived and designed the study. GP, MMP, AH, and JJM performed experiments. GP, CAF, JKF analyzed results. GP, CAF, and JKF wrote the manuscript, which all authors approved.

Declaration of interest: The authors report no conflicts of interest.

Tables

Table 1: Cell population frequencies in *cd79a:GFP* + *lck:mCherry* and *lck:GFP* zebrafish.

<i>cd79a:GFP</i> + <i>lck:mCherry</i>	Thymus	Scale	Marrow
Total Lymphoid Gate cells	9,449 cells	7,157 cells	17,562 cells
Population 1 (GFP^{hi}/mCh⁻)	10.0%	2.4%	18.2%
Population 2 (GFP^{lo}/mCh^{hi})	14.1%	1.7%	0.4%
Population 3 (GFP⁻/mCh^{hi})	32.8%	17.5%	2.2%
Population 4 (GFP⁻/mCh^{lo})	1.2%	14.2%	2.6%
GFP⁻/mCh⁻ cells	41.9%	64.2%	76.6%

<i>lck:GFP</i>	Thymus	Scale	Marrow
Total Lymphoid Gate cells	43,160 cells	8,176 cells	27,685 cells
GFP^{lo} cells	5.7%	22.0%	6.2%
GFP^{hi} cells	24.4%	0%	0%
GFP⁻ cells	69.9%	78%	93.8%

Table 2: Quantification of scale lymphocytes.

Genotype	<i>cd79a:GFP</i>		<i>cd79b:GFP</i>		<i>IgM1:GFP</i>	<i>WIK lck:GFP</i>		<i>Casper lck:GFP</i>		<i>lck:GFP + rag2:hMYC</i>	
Fluorescence	GFP ^{hi}	GFP ^{lo}	GFP ^{hi}	GFP ^{lo}	GFP ⁺	GFP ^{hi}	GFP ^{lo}	GFP ^{hi}	GFP ^{lo}	GFP ^{hi}	GFP ^{lo}
B cells/scale	34 (84%)	5 (8%)	6 (100%)	15 (50%)	10 (100%)		8 (12%)		7 (12%)		14 (15%)
T cells/scale		29 (50%)		6 (22%)			32 (50%)		29 (50%)		41 (43%)
BiP cells/scale	6 (16%)	21 (37%)		3 (9%)			24 (38%)		22 (38%)		30 (32%)
GFP^{hi} or GFP^{lo} cells/scale	40 ± 9	*58 ± 10	6 ± 1	*29 ± 9	10 ± 1		63 ± 6		58 ± 19		*95 ± 16
Lymphocytes/scale	98		35		10	63		58		95	

Average lymphocytes/scale (B, T, BiP) recovered after biopsy of different genotypes (totals are extrapolated based on each cell type % in scales Figures 3-4, Supplemental Figure 3C). Totals are means ± S.E.M. * "Other cells" in Figures 3-4 and Supplemental Figure 3C are omitted, so totals for some columns do not = 100% of total cells/scale.

Figure Legends

Figure 1: Zebrafish lymphocytes in scale epidermis. (A) Light and fluorescent microscopy images of wild-type (WT) or transgenic *cd79a:GFP*, *cd79b:GFP*, and *lck:GFP* fish. Yellow circle denotes thymic region. White bars = 2mm. **(B)** Top row: light microscopy images of single scales from each fish in panel 1A. DAPI highlights nuclei concentrated in caudal, water-exposed region of scales. Middle row: low-power confocal fluorescent images show GFP⁺ cells in the epidermis of all three transgenic lines. Bottom row: red-boxed regions in middle rows at high-power. White bars = 100 μm in light microscopy, DAPI, and low-power confocal images or 10 μm in high-power images.

Figure 2: Epidermal lymphocyte identities. (A) Flow cytometry work-flow showing example lymphoid and GFP⁺, GFP^{lo}, and GFP^{hi} gates in *lck:GFP* fish. **(B)** Fluorescent microscopy images and flow cytometry histograms of scale cells from B- (*cd79a:GFP*, *cd79b:GFP*) or T- (*lck:GFP*, *lck:GFP* + *rag2:hMYC*, *lck:mCherry*) labeled lines. Yellow ovals denote thymic region. White bars = 2mm. **(C)** Bulk qRT-PCR of FAC-sorted GFP⁺ cells from *cd79a:GFP* (n=2), *cd79b:GFP* (n=2), *lck:GFP* (n=4), or *lck:mCherry* (n=3) fish (40 scales/fish) using B- (*pax5*, *cd79b*, *ighm*, *ighz*), T- (*cd4*, *cd8*, *lck*), or lymphoblast- (*igic1s1*, *rag2*) specific genes. Results normalized to housekeeping genes *eef1a1l1* (*ef1a*) and *rpl13a*, shown as mean ± S.D.

Figure 3: Single-cell gene expression profiles of lymphocytes from *cd79*-labeled fish. (A) Transcript levels in GFP^{hi} and GFP^{lo} populations from *cd79a:GFP* thymic, scale, and marrow cells obtained using multiplex-qPCR. Labels at top list genotype, tissue, and GFP intensity of each sample type. Inferred cell identities are below heatmaps with total cell number and percentage.

Figures

Cell identifies are color-coded in legend below figure. **(B)** Dot-plots depicting expression levels of genes listed on X- and Y-axes. Each dot is one cell from the heatmap in **A**. **(C-D)** Identical data depictions as in **A** and **B**, with results for *cd79b:GFP* fish. Expression of *eef1a1/1* (*ef1a*; bottom heatmap row) was used as a threshold to confirm wells contained amplifiable RNA. CT values converted to Log₂Ex for visualization of relative expression levels.

Figure 4: Single-cell profiles of lymphocytes from *cd79a:GFP* + *lck:mCherry* and *lck:GFP* fish. (A) Fluorescent microscopy images and flow plots of thymus, scale, and marrow from *cd79a:GFP* + *lck:mCherry* fish. Yellow oval denotes thymic region. White bars = 2mm. Populations 1-4 are described in the main text. **(B)** Transcript levels in Populations 1-4 from each tissue (left, thymus; middle, scale; right, marrow). Data depiction identical to Figures **3A** and **3C**. **(C)** Same format as in **A**, with results for *lck:GFP* fish. Propidium iodide (PI; Y-axis) used to verify viability. **(D)** Data depiction identical to **B**, with transcript levels for GFP^{lo} and GFP^{hi} cells. Black boxes in center (scale) column indicate genes not tested.

Figure 5: Quantifying scale epidermal lymphocytes. FAC-sorted lymphocytes recovered post-biopsy of **(A)** B- or **(B)** T-lineage labeled lines. WT scales (*WIK* genotype) were auto-fluorescence controls. Bars indicate number of GFP^{hi} or GFP^{lo} cells/scale. Each dot is one scale. Pairwise comparisons to identify significantly different pairs of means were performed using Dunn's test. *p*-values: *<0.05, **<0.005, ***<0.0005, ****<0.0001.

Figures

Figure 6: scRNAseq and lineage-specific gene signatures of *lck:GFP* lymphocytes. (A) UMAP plot of GFP⁺ cells from thymus, scale, and marrow (merged) from *lck:GFP* fish. Cluster analysis showed 13 populations; cell number for each is listed at right. **(B)** Violin plot distributions of T-, B-, and NK-lineage single-cell gene signature scores for each cluster (estimated using Seurat and UCell). Violin plots are color-coded according to UMAP and legend colors above.

Figure 7: Epidermal lymphocyte DXM responses. (A) *cd79a:GFP*, **(B)** *cd79b:GFP*, **(C)** *lck:GFP*, **(D)** *lck:mCherry*, **(E)** *cd79a:GFP* + *lck:mCherry*, and **(F)** *cd79b:GFP* + *lck:mCherry* fish before and after 10 days of continuous DXM immersion. Top panels: pre- and post-DXM fluorescent microscopy images; fluorescence-integrated density histograms at right. Yellow ovals denote thymic region; white bars = 2mm. Bottom panels: flow cytometry plots of biopsies pre- and post-DXM (5 scales/biopsy), with histograms of lymphocytes/5 scales at right. Gates, cells/gate, and % of total cells are shown in flow plots. Three **(A-D)** or two **(E, F)** fish tested for each genotype. Repeated measures two-way ANOVAs used Sidak's multiple-comparison test. *p*-values: **p*<0.05, ***p*<0.005, ****p*<0.0005, *****p*<0.0001.

Figure 8: Phagocytosis by zebrafish lymphocytes. (A) Results for lymphocytes (GFP^{hi} or GFP^{lo}) from each tissue (thymus, scale, or marrow), with total cells tested and percent (+) for red-bead ingestion. Brightfield images show example cells with ≥1 attached/internalized bead. Fluorescent micrographs show merged GFP + red (bead) images. White bars = 10μm. Red font indicates samples with highest phagocytic activity. **(B)** Histograms of phagocytosis results in panel A, grouped by predominant cell type. Asterisks denote samples labeled red in panel A. **(C)**

Figures

75 Comparison of each cell type (B, T, or mixed B + T). Groups are based on single-cell expression
76 results in **Figures 3-4**.
