## Abstract

**Objectives:** We hypothesized that systemic administration of high-mobility group box 1 fragment attenuates the progression of myocardial fibrosis and cardiac dysfunction in a hamster model of dilated cardiomyopathy by recruiting bone marrow mesenchymal stem cells thus causing enhancement of a self-regeneration system.

**Methods:** Twenty-week-old J2N-k hamsters, which are  $\delta$ -sarcoglycan-deficient, were treated with systemic injection of high-mobility group box 1 fragment (HMGB1, n=15) or phosphate buffered saline (control, n=11). Echocardiography for left ventricular function, cardiac histology, and molecular biology were analyzed. The life-prolonging effect was assessed separately using the HMGB1 and control groups, in addition to a monthly HMGB1 group which received monthly systemic injections of high-mobility group box 1 fragment, 3 times (HMGB1, n=11, control, n=9, monthly HMGB1, n=9).

**Results:** The HMGB1 group showed improved left ventricular ejection fraction, reduced myocardial fibrosis, and increased capillary density. The number of platelet-derived growth factor receptor-alpha and CD106 positive mesenchymal stem cells detected in the myocardium was significantly increased, and intra-myocardial expression of tumor necrosis factor  $\alpha$  stimulating gene 6, hepatic growth factor, and vascular endothelial growth factor were

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 3

significantly upregulated after high-mobility group box 1 fragment administration. Improved

survival was observed in the monthly HMGB1 group compared with the control group.

**Conclusions:** Systemic high-mobility group box 1 fragment administration attenuates the

progression of left ventricular remodeling in a hamster model of dilated cardiomyopathy by

enhanced homing of bone marrow mesenchymal stem cells into damaged myocardium,

suggesting that high-mobility group box 1 fragment could be a new treatment for dilated

cardiomyopathy.

## Introduction

Dilated cardiomyopathy (DCM) is one of the most common causes of heart failure and is associated with left ventricular dilatation and contractile dysfunction [1]. While significant improvements have been made in medical therapies, such as angiotensin-converting enzyme inhibitors and beta-blockers [2], and interventions, such as implantable cardioverter defibrillators [3] and cardiac resynchronization therapy [4], the prognosis for heart failure patients is still poor with 1-year mortality of 25–30% and a 50% survival rate at 5 years [5]. DCM remains the most common indication for cardiac transplantation but donor shortages have become a serious issue. To deal with this problem, several novel approaches using cell therapy have been developed in DCM patients with encouraging results [6–8].

Stem cells are an endogenous physiological healing mechanism of the body. A number of reports have suggested that damaged tissues may release various cytokines, which facilitate not only the mobilization of bone marrow-derived mesenchymal stem cells (BMMSCs) into the peripheral blood, but also their homing to sites of wound healing [9–11]. The enhancement of such healing mechanisms by drug administration might have beneficial effects in various diseases.

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 5

High-mobility group box 1 (HMGB1) is a non-histone nuclear protein that regulates chromatin structure remodeling by acting as a molecular chaperone in the chromatin DNA-protein complex [12]. Previous reports have demonstrated that endogenous platelet-derived growth factor receptor-alpha positive (PDGFR $\alpha$ <sup>+</sup>) BMSCs accumulate in damaged tissue and contribute to regeneration in response to elevated HMGB1 levels in serum [13]. Moreover, systemic administration of HMGB1 further induces the accumulation of PDGFR $\alpha$ <sup>+</sup> BMSCs in the damaged tissue through CXCR4 upregulation, which is followed by significant inflammatory suppression [14].

Since BMSCs have been reported to have therapeutic effect in DCM through paracrine effects [6,7], the above-mentioned “drug-induced endogenous regenerative therapy” might have effectiveness for DCM without supply of viable ex vivo cells. Recently, we developed a HMGB1 fragment containing the mesenchymal stem cell mobilization domain from human HMGB1. We hypothesize that systemic administration of this HMGB1 fragment attenuates the progression of myocardial fibrosis and cardiac dysfunction in a hamster model of DCM by recruitment of BMSCs, promoting self-regeneration.

## Material and Methods

Animal procedures were carried out under the approval of the Institutional Ethics Committee (reference number 28-011-002). The investigation conformed to the “Principles of Laboratory Animal Care” formulated by the National Society for Medical Research and the “Guide for the Care and Use of Laboratory Animals” (National Institutes of Health Publication). All experimental procedures and evaluations were performed in a blinded manner.

### *Experimental Animals*

Male J2N-k hamsters, which are deficient in  $\delta$ -sarcoglycan, were used for this study. J2N-k hamsters are an established animal model of DCM. They exhibit progressive myocardial fibrosis and moderate cardiac dysfunction at 8–9 weeks of age. Accordingly, the average life span of J2N-k hamsters is much shorter (approximately 42 weeks) than control hamsters (approximately 112 weeks) [15,16].

### *HMGB1 Fragment*

Mesenchymal stem cell mobilization domain from human HMGB1 was produced as “HMGB1 fragment” by solid-phase synthesis and provided by StemRIM (StemRIM Inc., Osaka, Japan).

## High mobility group box 1 in dilated cardiomyopathy. Kido et al. 7

108 The HMGB1 fragment was dissolved in phosphate buffered saline (PBS) to a concentration of 1  
109 mg/ml before administration.

110

### 111 *Procedure of HMGB1 Fragment Administration*

112 Male 19-week-old J2N-k hamsters were purchased from Japan SLC (Shizuoka, Japan). HMGB1  
113 fragment (3mg/kg/day; HMGB1, n= 15) or PBS (3ml/kg/day; control, n=11) was administered  
114 for 4 consecutive days at the age of 20 weeks in the following manner: The external jugular vein  
115 was exposed by a median neck skin incision under 1.5% isoflurane anesthesia. Subsequently,  
116 HMGB1 fragment or PBS was injected through the external jugular vein. After the complete  
117 hemostasis, the skin incision was closed, and the hamsters were housed in a  
118 temperature-controlled cage.

119

### 120 *Transthoracic Echocardiography*

121 Transthoracic echocardiography was performed to assess cardiac function using M-mode  
122 echocardiography with Vivid I (GE Healthcare) under isoflurane inhalation (1%). Diastolic and  
123 systolic dimensions of the left ventricle (LVDd/Ds), and left ventricular ejection fraction  
124 (LVEF) were measured before treatment, and reassessed at 4 and 6 weeks after treatment.

125

126 *Histological Analysis*

127 The heart was excised under isoflurane anesthesia (5%) 6 weeks after treatment to perform  
 128 histological and molecular biological analysis. The excised heart was fixed with either 10%  
 129 buffered formalin for paraffin sections or 4% paraformaldehyde for frozen sections. The  
 130 paraffin sections were stained with picosirius red to assess the degree of myocardial fibrosis.  
 131 The paraffin sections were used for immunohistochemistry and labeled using polyclonal CD31  
 132 antibody (1:50 CD31, Abcam, Cambridge, UK), anti- $\alpha$ -sarcoglycan (clone: Ad1/20A6;  
 133 Novocastra, Weltzar, Germany), and anti- $\alpha$ -dystroglycan (clone: VIA4-1; Upstate  
 134 Biotechnology, Lake Placid, NY) to assess capillary vascular density and the organization of  
 135 cytoskeletal proteins. The paraffin sections were also labeled using rabbit monoclonal  
 136 anti-CD106 antibody (ab134047, Abcam, Cambridge, MA) and goat polyclonal anti-PDGFR $\alpha$   
 137 (R&D). PDGFR $\alpha$  and CD106 are known to be expressed in BMMSCs and are commonly used  
 138 as markers for mesenchymal stem cells (MSCs) [17,18]. The frozen sections were also used for  
 139 immunohistochemistry and labeled with rabbit polyclonal anti-SDF1 antibody (ab9797, Abcam,  
 140 Cambridge, MA) and mouse monoclonal CXCR4 antibody (4G10, sc-53534, Santa Cruz  
 141 Biotechnology). The frozen sections were also stained with 4-hydroxynonenal to estimate lipid  
 142 peroxidation [19], and dihydroethidium to estimate superoxide production [20].

143

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 9

144 More than 5 sections were prepared per specimen and 3 low power fields per section were  
145 analyzed and averaged. The fibrotic area, the expression of  $\alpha$ -sarcoglycan and  $\alpha$ -dystroglycan,  
146 and the 4-hydroxynonenal positive area were measured using Metamorph image analysis  
147 software (Molecular Devices, Inc., Downingtown, PA). The capillary density, the number of  
148 PDGFR $\alpha$ <sup>+</sup> and CD106 positive (CD106<sup>+</sup>) cells, the number of CXCR4 positive (CXCR4<sup>+</sup>) cells  
149 and SDF-1 positive area (mm<sup>2</sup>), and the number of dihydroethidium positive dots were  
150 measured using the BZ-analysis software (Keyence, Tokyo, Japan).

151

## 152 *Transmission electron microscopy*

153 Cardiac tissue was pre-fixed with Karnovsky fixative containing 2.5% glutaraldehyde, 2%  
154 paraformaldehyde in a 0.1 M (pH 7.4) cacodylate buffer for 2 hours at 4°C and post-fixed with  
155 2% osmium tetroxide for 2 hours at 4°C. The samples were then immersed in 0.5% uranyl  
156 acetate for 3 hours at room temperature, dehydrated in ethanol (50%, 70%, 80%, 90%, 95%, and  
157 100%) and propylene oxide, and embedded in epoxy resin. Semithin sections (0.5 $\mu$ m) were  
158 stained with 0.1% toluidine blue solution and examined under a light microscope. Ultrathin  
159 sections were made with a Leica ultramicrotome. These sections were counterstained with  
160 uranyl acetate and lead citrate, before examination with a Hitachi H-7100 electron microscope  
161 at 75 kV.

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 10

162

163 *Real-Time Polymerase Chain Reaction*

164 Total RNA was extracted from cardiac tissue and reverse transcribed using Omniscript reverse

165 transcriptase (Quiagen, Hilden, Germany). The resulting cDNA was used for real-time

166 polymerase chain reaction with the ABI PRISM 7700 system (Applied Biosystems) and

167 Taqman Universal Master Mix (Applied Biosystems, Division of Life Technologies

168 Corporation, Carlsbad, Calif) and using hamster-specific primers for tumor necrosis factor- $\alpha$

169 stimulating gene 6 (TSG-6), vascular endothelial growth factor (VEGF), and CXCR4. Each

170 sample was analyzed in duplicate for each gene studied. Data were normalized to

171 glyceraldehyde-3-phosphate dehydrogenase expression level. For relative expression analysis,

172 the ddCT method was used, and a sample from a control hamster was used as reference. The

173 real-time polymerase reaction was also conducted using Fast SYBR Green Master Mix and

174 primers designed for hepatic growth factor and glyceraldehyde-3-phosphate dehydrogenase as

175 shown in Table 1. For relative expression analysis, we prepared a 5-fold serial standard curve

176 using a sample from a HMGB1 hamster as reference.

### *Evaluation of hamster prognosis after treatment*

The life-prolonging effect of the HMGB1 fragment on J2N-k hamsters was assessed separately. Twenty-week-old J2N-k hamsters were treated with HMGB1 (HMGB1, n= 11) or PBS (control, n= 9) as described above. An additional treatment group received monthly administration of HMGB1 fragment 3 times, (monthly HMGB1, n= 9) to evaluate the long-term therapeutic effects of HMGB1 fragment (Fig 1). The animals were randomly allocated to each treatment group and housed after the initial treatment. The survival rate in the 3 groups was calculated by the Kaplan–Meier method using JMP Pro 12 (SAS Institute, Cary, NC, USA) and the significant difference between the groups was tested at 22 weeks (equal to 42 weeks of age, the average lifespan of J2N-k hamsters) by log-rank analysis.

### *Statistical Analysis*

Continuous variables were summarized as means with standard deviations and compared using an unpaired t-test. Survival curves were prepared using the Kaplan–Meier method and compared using the log-rank test. All data were analyzed using JMP Pro 12. Differences were considered statistically significant at P-values < 0.05.

## Results

### *Preserved Cardiac Performance with HMGB1 Fragment Administration*

The functional effects of HMGB1 fragment on the DCM heart were assessed by transthoracic echocardiography over time. LVDd/Ds and LVEF at 20 weeks of age, just before the treatment, were not significantly different between the HMGB1 group and the control group. After treatment, echocardiography showed that the LVEF was significantly preserved until 6 weeks in the HMGB1 group compared with the control group (4 weeks:  $43 \pm 8\%$  vs  $33 \pm 9\%$ ,  $p=0.01$ ; 6 weeks:  $41 \pm 7\%$  vs  $31 \pm 7\%$ ,  $p=0.0001$ , HMGB1 vs control, respectively) (Fig 1).

### **Fig 1.**

Changes in LVEF (a), LVDd (b), and LVDs (c) over time after the treatment.

Diastolic and systolic dimensions of the left ventricle, and LVEF were measured before treatment, and reassessed at 4 and 6 weeks after treatment. The LVEF was significantly preserved until 6 weeks after the treatment in the HMGB1 group compared with the control group.

LVEF, left ventricular ejection fraction; LVDd, left ventricular diastolic dimension; LVDs, left ventricular systolic dimension.

## 218 *Effect of HMGB1 Fragment on Myocardial Fibrosis*

219 The degree of myocardial fibrosis 6 weeks after HMGB1 fragment treatment was assessed by  
220 picrosirius red staining and compared with control group. Quantification of fibrotic area  
221 confirmed that the degree of myocardial fibrosis was significantly reduced in the HMGB1 group  
222 compared with the control group ( $16.6 \pm 3.8\%$  vs  $22.7 \pm 5.4\%$ , respectively,  $p=0.04$ ) (Fig 2).

223

## 224 **Fig 2.**

231

## 232 *Increased Vasculature in the Heart After HMGB1 Fragment Administration*

233 Capillary vascular densities 6 weeks after the treatment were assessed by CD31  
234 immunostaining. In the HMGB1 group, the number of CD31 positive arterioles and capillaries

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 15

was significantly increased compared with the control group ( $654 \pm 171$  units/mm<sup>2</sup> vs  $484 \pm 74$  units/mm<sup>2</sup>, respectively,  $p=0.02$ ) (Fig 3).

(b), Tissue sections were immunostained for CD31 and the capillary density was measured with the analysis software. The HMGB1 group showed significantly higher capillary vascular density than the control group.

HMGB1, high-mobility group box 1.

## *PDGFR $\alpha$ and CD106 Positive Cells in the Hearts*

Immunohistochemistry showed that the number of PDGFR $\alpha$ <sup>+</sup> and CD106<sup>+</sup> cells in the heart tissue was significantly greater in HMGB1 group compared with the control group ( $12 \pm 5$  cells/field vs  $4 \pm 2$  cells/field, respectively,  $p<0.001$ ) (Fig 4).

## **Fig 4.**

260

## 261 *Increased CXCR4 Positive Cells in the Heart after HMGB1 Fragment Administration*

262 Immunohistochemistry showed significantly increased ratio of the number of CXCR4<sup>+</sup> cells to  
263 SDF-1 positive area (mm<sup>2</sup>) in heart tissue in the HMGB1 group than in the control group  
264 (1.3 $\pm$ 1.0 vs 0.3 $\pm$ 0.1 cells/mm<sup>2</sup>, respectively, p=0.02) (Fig 5).

276

## 277 *Preservation of Cytoskeletal Proteins after HMGB1 Fragment Administration*

278 Immunohistochemistry showed increased expression of  $\alpha$ -sarcoglycan and  $\alpha$ -dystroglycan in the  
279 basement membrane beneath the cardiomyocytes in HMGB1 group, whereas lower expression  
280 levels of these proteins was seen in the control group ( $\alpha$ -sarcoglycan,  $12.2 \pm 2.7\%$  vs  $2.8 \pm 1.4\%$ ,  
281  $p < 0.001$ ,  $\alpha$ -dystroglycan,  $20.2 \pm 3.5\%$  vs  $8.3 \pm 1.8\%$ ,  $p < 0.001$ , HMGB1 vs control, respectively)  
282 (Fig 6).

291

## 292 *Mitochondrial Ultramicrostructure*

293 Transmission electron microscopy of the myocardium showed a relatively regular arrangement  
294 of mitochondrial cristae in the HMGB1 group. In contrast, the mitochondrial cristae were  
295 disordered in the control group (Fig 7).

296

## 297 **Fig 7.**

298 Mitochondrial ultramicrostructure was detected by TEM. Representative image ( $\times 12000$ ) of  
299 mitochondrial morphology and cristae of myocardium in the HMGB1 group and the control  
300 group. The HMGB1 group showed relatively regular arrangement of mitochondrial cristae  
301 compared with the control group.

302 TEM, Transmission electron microscopy; HMGB1, high-mobility group box 1.

303

304 *Effect of HMGB1 Fragment on Oxidative Stress in the Hearts*

305 The lipid peroxidation and superoxide production were assessed by 4-hydroxynonenal staining  
 306 and dihydroethidium staining, respectively. The results showed a trend towards reduced lipid  
 307 peroxidation ( $3.5 \pm 2.4\%$  vs  $5.6 \pm 3.7\%$ ,  $p = 0.06$ , HMGB1 vs control) and a significant reduction  
 308 in superoxide production in the HMGB1 group compared with control ( $219 \pm 32$  units/ $\text{mm}^2$  vs  
 309  $1185 \pm 97$  units/ $\text{mm}^2$ , respectively,  $p < 0.0001$ ) (Fig 8).

310

 314 4-hydroxynonenal staining ( $\times 100$ , scale bar= $50\mu\text{m}$ ) (b).

315 Tissue sections were stained with dihydroethidium to estimate superoxide production, and  
 316 4-hydroxynonenal to estimate lipid peroxidation. The HMGB1 group showed significantly  
 317 reduced production of superoxide (c) and a trend towards reduced lipid peroxidation (d)  
 318 compared with the control group.

319 HMGB1, high-mobility group box 1.

320

### *Upregulated TSG-6, VEGF, HGF, and CXCR4 in the Heart after HMGB1 Fragment*

#### *Administration*

Real-time PCR was used to quantitatively assess the expression levels of BMMSC-derived factors, such as VEGF, TSG-6, HGF, and CXCR4. Intramyocardial mRNA levels of VEGF, TSG-6, and HGF were significantly upregulated in HMGB1 group compared with the control group (TSG-6,  $1.5 \pm 0.6$  vs  $1.1 \pm 0.2$ ,  $p = 0.03$ , VEGF,  $1.3 \pm 0.4$  vs  $1.0 \pm 0.2$ ,  $p = 0.04$ , HGF,  $3.2 \pm 2.3$  vs  $1.3 \pm 0.6$ ,  $p = 0.02$ , HMGB1 vs control, respectively). The intramyocardial mRNA levels of CXCR4 in the HMGB1 group showed a trend towards increased expression compared with control ( $1.5 \pm 0.4$  vs  $1.2 \pm 0.3$ , respectively,  $p = 0.06$ ).

#### *Survival Benefit of Monthly HMGB1 Administration*

Survival of J2N-k hamsters was assessed using the Kaplan–Meier method. There was no significant difference in survival between HMGB1 and control. In contrast, the monthly HMGB1 group all survived to the full 42 weeks, and they showed significantly improved survival rate compared with control group (log-rank  $p = 0.001$ ) (Fig 9).

### **Fig 9.**

Survival after each treatment assessed by the Kaplan–Meier method.

High mobility group box 1 in dilated cardiomyopathy. Kido et al. 21

339 There was no significant difference between the single HMGB1 treatment (n=11) group and the  
340 control group (n=9), whereas the monthly HMGB1 group (n=9) showed a significantly greater  
341 survival rate than control (p=0.01).

342

## Discussion

In the present study we have shown that, first, systemic administration of HMGB1 fragment leads to the accumulation of PDGFR $\alpha$ <sup>+</sup> and CD106<sup>+</sup> cells in damaged myocardium possibly through the SDF-1/CXCR4 axis and upregulated expression of cardioprotective factors such as TSG-6, VEGF, and HGF in the heart tissue of J2N-k hamsters. Second, the myocardial histology in the HMGB1 group demonstrated significantly decreased fibrosis, increased capillary vascular density, decreased oxidative stress, and well-organized cytoskeletal proteins compared with the control group. Finally, cardiac function was significantly preserved after HMGB1 fragment administration and the survival benefit was shown with monthly HMGB1 fragment treatment.

The present study demonstrates the feasibility of “drug-induced endogenous regenerative therapy” using an HMGB1 fragment in a hamster model of DCM . While the precise mechanism remains unclear, it is well known that HMGB1 acts as a chemoattractant for MSCs [13,14,21]. Systemic HMGB1 administration has been reported to induce accumulation of PDGFR $\alpha$ <sup>+</sup> cells around blood vessels in the bone marrow and significant increases in these cells in the peripheral blood [13]. In addition, the enhancement of CXCR4 expression with HMGB1

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 23

360 treatment promotes the local migration to damaged tissue through the SDF-1/CXCR4 axis,  
361 which might be essential in DCM [22] as well as ischemic cardiomyopathy [23–25].  
362  
363 While PDGFR $\alpha$ <sup>+</sup> BMSCs might be the predominant cell population mobilized by  
364 administration of HMGB1 fragment and therefore exerting therapeutic effects on damaged  
365 myocardium, it has been suggested that PDGFR $\alpha$ <sup>+</sup> MSCs include other defined subpopulations  
366 with distinct functions [26]. As HMGB1 is also reported to induce other cell types [27], the  
367 accumulated cells in damaged heart tissue after HMGB1 administration might be highly  
368 heterogeneous and it will therefore be important to identify in the future, specific PDGFR $\alpha$ <sup>+</sup>  
369 subpopulations induced by HMGB1 which have therapeutic benefits.  
370  
371 Paracrine signaling is a well-investigated mechanism of protective effects exhibited by  
372 BMSCs on surrounding cells [28–32]. TSG-6 plays a key role in the anti-inflammatory effects  
373 of BMSCs [31,33]. TSG-6 attenuates oxidative stress through activation of CD44 [34,35], and  
374 downregulates TGF- $\beta$  by suppressing plasmin activity [33], which could result in decreased  
375 myocardial fibrosis. Since increased oxidative stress is one of the essential factors in the  
376 pathogenesis of myocardial fibrotic changes in J2N-k hamsters [16], our results suggest that  
377 HMGB1 fragment administration could become a substantial therapy for DCM. VEGF has been

# High mobility group box 1 in dilated cardiomyopathy. Kido et al. 24

known to promote angiogenesis in ischemic conditions [29,36,37], which might have a beneficial effect on the defective vascularization within the left ventricle, which is associated with the pathophysiology of DCM [38,39]. HGF is known to be a putative paracrine mediator in cardiac repair mechanisms of BMSCs [40]. Our group has previously reported that HGF induced the appropriate microenvironment for extracellular matrix remodeling, including strong expression of cytoskeletal proteins in damaged myocardium [41,42].

No significant difference in survival was observed between the HMGB1 and control groups, however, animals that received monthly HMGB1 treatment showed significantly better survival compared with control. The therapeutic benefits of HMGB1 fragment might be sustained by repeated administration in J2N-k hamsters and further investigation concerning the optimal dose and interval of administration of HMGB1 fragment will be needed for the clinical use of HMGB1 fragment in DCM patients.

## Conclusion

Systemic HMGB1 fragment administration attenuates the progression of left ventricular remodeling in a hamster model of DCM by enhanced homing of BMMSCs into damaged myocardium, suggesting that HMGB1 fragment could be beneficial in the treatment of DCM.
