## Abstract

The jaguar (*Panthera onca*) is widely distributed across a broad range of habitat types, where its feeding habits and habitat use patterns vary significantly. The jaguar and its main arboreal preys – the brown-throated sloth (*Bradypus variegatus*) and the red howler monkey (*Alouatta juara*) – are widespread in the Amazonian floodplain forests Mamirauá Reserve. These forest-dwelling species are the most common mammal species both in the continuous forest and the forest patches surrounded by a river matrix – the fluvial islands – at Solimões and Japurá rivers. We used sign surveys along line-transects to assess the pattern of habitat occupancy by jaguars in Amazonian floodplain forests. Specifically, we (i) tested whether habitat occupancy by jaguars differs between river islands and continuous forest; and (ii) evaluated whether and how the local abundance of sloths and howler monkeys influence the probability of site occupancy by jaguars. We built an occupancy model and used Bayesian inference to reach these goals. The proportion of sites estimated to be used by jaguars was  $\psi = 0.75$  (HPD95: 0.36–1.00), and it did not differ between islands and continuous forest. The abundance of both prey species had a direct influence on jaguar's habitat use, whereas the aquatic matrix seems to have a negligible effect on the use of islands by jaguars. We conclude that prey search modulates jaguars' habitat occupancy patterns with both prey species having a similar effect. This finding reinforces the importance of sloths to the diet of jaguars in the study region despite its lower abundance than howlers. Finally, we suggest that sign surveys are an alternative method to assess the pattern of jaguar habitat occupancy in floodplain forests.

**Keywords:** Bayesian inference; hierarchical models; howler monkeys; occupancy modelling; predator-prey interaction; sloths.

# <sup>1</sup> Introduction

<sup>2</sup> Predation is a remarkable interspecific interaction that has long interested ecologists  
<sup>3</sup> (Gause et al., 1936). Large carnivores are prominent top predators that prevent prey  
<sup>4</sup> populations to overcrowd and deplete their food sources, and whose demise can initiate  
<sup>5</sup> substantial cascading ecological effects in the food chain that compromise ecosystem  
<sup>6</sup> structure and functioning (Ripple et al., 2014). Therefore, assessments of carnivore  
<sup>7</sup> distribution and population size are essential for developing informed conservation actions  
<sup>8</sup> for these species and their ecosystems.

<sup>9</sup> Jaguars (*Panthera onca*) are the largest American felids. They are widely distributed  
<sup>10</sup> across a broad range of habitat types (Sanderson et al., 2002), where their feeding habits  
<sup>11</sup> and habitat use patterns vary significantly (Astete et al., 2007; Morato et al., 2016). They  
<sup>12</sup> are opportunistic predators that exploit most of their medium to large terrestrial prey  
<sup>13</sup> species (González and Miller, 2002) according to their availability (Rabinowitz and  
<sup>14</sup> Nottingham, 1986). The species is often range resident and move over long daily distances  
<sup>15</sup> (2.3–16.4 km) in highly variable home ranges (8.8–718.6 km<sup>2</sup>; Morato et al., 2016).

<sup>16</sup> Jaguars' predominant terrestriality does not preclude them from occurring in  
<sup>17</sup> Amazonian seasonally flooded forests (herein *várzea* forests). This is the case at the  
<sup>18</sup> Mamirauá Sustainable Development Reserve – a protected area of *várzea* forests in Central  
<sup>19</sup> Amazon – where jaguars reach high densities probably because of high prey abundance  
<sup>20</sup> (Ramalho, 2012). The availability of arboreal (e.g., sloths and monkeys; Rabelo et al., 2017)  
<sup>21</sup> and water-associated (e.g., caimans and their eggs; Ramalho, 2012; Torralvo et al., 2017)  
<sup>22</sup> prey species allows jaguars to reside yearlong in flooded forests, including the 4- to 6-  
<sup>23</sup> month-long high-water season (Ramalho et al., 2009; Ramalho, 2012).

<sup>24</sup> Red howler monkeys (*Alouatta juara*), brown-throated sloths (*Bradypus variegatus*)  
<sup>25</sup> and jaguars are the most common mammal species in both the continuous forest and the  
<sup>26</sup> fluvial islands (Rabelo et al., 2019). These islands originate from a complex river dynamics,  
<sup>27</sup> in which the deposition of sediments as sandbars in the river channel that are followed by  
<sup>28</sup> primary succession (Kalliola et al., 1991). Therefore, island colonization by howlers, sloths  
<sup>29</sup> and jaguars requires that they move through other land cover types, including the crossing  
<sup>30</sup> of inhospitable water bodies by swimming (see Holt, 1932; Nunes, 2014).

<sup>31</sup> Several factors influence the success of this dispersal through the matrix, including  
<sup>32</sup> the distance to be crossed, the matrix permeability to the species movement and the  
<sup>33</sup> disperser's motivation to find food resources in the new habitat (Lima and Zollner, 1996).  
<sup>34</sup> Thus, given that jaguar can use and easily move through a wide range of land cover types  
<sup>35</sup> (Morato et al. 2018), it is plausible to expect that the search for prey plays a major role in  
<sup>36</sup> their dispersal across rivers to reach fluvial islands.

37 Here we developed an occupancy modelling study of the pattern of habitat  
38 occupancy of Amazonian *várzea* forests by jaguars to test the influence of prey  
39 availability on it. We used jaguar sign surveys along line-transects together with  
40 records of two important prey species, the brown-throated sloth and the red howler  
41 monkey, to evaluate their patterns of habitat use and co-occurrence using a Bayesian  
42 occupancy modelling (Royle and Dorazio, 2008). Specifically, we (i) compare habitat  
43 use by jaguars in sites embedded in islands and the continuous forest, and (ii) evaluate  
44 whether the local relative abundance of both prey species influences the probability of  
45 habitat use by jaguars. We hypothesize that jaguars' habitat use is similar in islands  
46 and continuous forest, and that prey abundances are strong predictors of it.

## 47 Methods

### 48 Study area

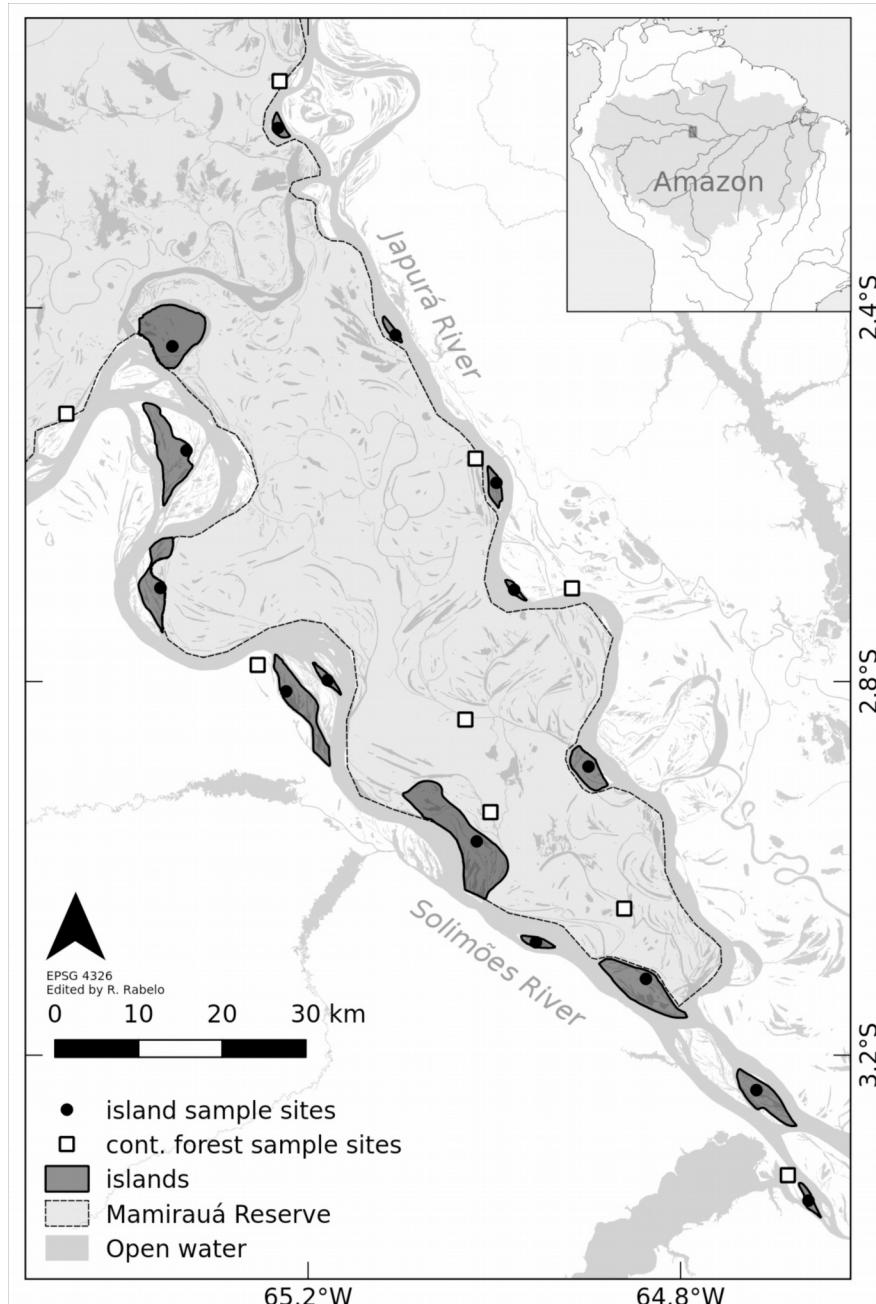

49 Our study region comprises the *várzea* forest, a floodplain forest ecosystem  
50 located at the confluence of the Solimões and Japurá rivers in Central Amazon (Fig.  
51 1). The interfluvium at these rivers' junction is protected by the Mamirauá  
52 Sustainable Development Reserve (IDSM, 2010). *Várzea* forests are seasonally flooded  
53 by nutrient-rich white-water rivers, whose average annual water level range is 12 m  
54 (Ramalho et al., 2009). The maximum water level is reached around June and its  
55 minimum between October and November (IDSM, 2010).

56 River dynamics constantly modifies the spatial structure of these riverscapes by  
57 the erosion of margins and the transport and deposition of sediments (Peixoto et al.,  
58 2009). This process creates fluvial islands that emerge and can disappear in a few  
59 decades (Kalliola et al., 1991). Although some islands represent ephemeral habitat  
60 patches for mammals with long generation times, such as jaguars, these species often  
61 use them (Rabelo et al., 2019).

### 62 Sampling design and data collection

63 We sampled 14 focal islands ranging from 151 to 3,625 ha and nine independent  
64 sample sites embedded in the adjacent continuous forest (Fig. 1). We chose islands (i)  
65 permanently surrounded by the water matrix (that is, even during the low-water  
66 season), (ii) whose edge was at least 2 km distant from the edge of the nearest sampled  
67 island to avoid sampling islands that are too close to each other, and (iii)  $\geq 30$  years-  
68 old (island age was determined using a historical series of Landsat Thematic Mapper

69 satellite images) to avoid islands that are too ephemeral for our study species (jaguar  
70 generation time: ~7 years, de la Torre et al., 2018). Although we believe that jaguars  
71 can visit islands younger than 30-years old during their daily journeys, it is unlikely  
72 that these islands have an adequate forest structure to harbor arboreal mammals, as  
73 most islands younger than 30 years are dominated by pioneer vegetation and rarely  
74 present late-succession forest patches (Peixoto et al. 2009).

75 **Figure 1.** Map of the study region showing the distribution of sample sites in the  
76 Central Amazonia floodplain forest landscape.

77 We sampled mammals along line-transects that are independent sample sites.  
78 Transect length on islands varied from 1.2 km to 11.6 km and it was directly  
79 correlated to island size (Pearson correlation:  $r = 0.94$ ,  $P < 0.001$ ), making island size  
80 an intrinsic characteristic of each sample. We established line-transects with the same  
81 length range within the continuous forest sample sites to survey species. Surveys  
82 consisted of quiet walks on trails by two trained observers at *ca.* 1.5 km/h following a  
83 standardized protocol (Peres, 1999). We carried out the surveys in the morning (0630–  
84 1130 h) and afternoon (1300–1700 h). We stopped surveying when it was raining. We  
85 recorded sloths and howler monkeys via sighting and vestiges (e.g., calls and feces)  
86 and jaguars via fresh feces and footprints (recorded signs were marked to avoid  
87 double detection). Although some researchers can argue that the other wild  
88 Amazonian big cat (puma, *Puma concolor*) could be responsible for the vestiges, no  
89 records of this species were obtained in an effort of 2,040 camera\*day at Mamirauá  
90 Reserve (Alvarenga et al., 2018). Therefore, we assumed that there is no resident  
91 puma population in the reserve. We conducted four replicate surveys per transect (i.e.,  
92 four occasions), separated by one to four days, during the low-water season  
93 (September to November) of either 2013 or 2014. We limited surveys to the low-water  
94 season to minimize potential seasonal effects on species detection. We were unable to  
95 visit all sample sites during a single low-water season due to logistical constraints.

## 96 Data analysis

97 We assessed the pattern of jaguar occurrence across our sample sites using an  
98 occupancy modelling approach. This approach estimates the probability of a site  
99 being occupied/used ( $\psi$ ) by a given species when its detection is imperfect, that is,  
100 when the detection probability is less than 1 (Mackenzie et al., 2006). Given that the  
101 non-detection of a species at a sample site results from either its true absence or the  
102 failure to detect it, repeated surveys (occasions) on multiple sample sites are used to  
103 estimate the detection probability ( $p$ ) of a species conditional on occupancy. In our  
104 model, the occurrence of jaguar at a given site “ $j$ ” of type “ $k$ ” (i.e., island or  
105 continuous forest) is denoted as  $O_{jk}$  (i.e., the true occupancy state: 1 if present, 0  
106 otherwise), and is the outcome of a Bernoulli trial with probability of occupancy  $\psi_{jk}$ ,

$$107 \quad O_{jk} \sim \text{Bernoulli}(\psi_{jk})$$

108 Similarly, the binomial detection/non-detection (1 = present; 0 = not detected)  
109 of jaguars ( $D$ ) during a given occasion “ $i$ ” and in a given sample site “ $j$ ” are input in  
110 the form of an array  $D_{ij}$ . Therefore, whether the species is detected during a given  
111 occasion in a given site is conditional on the occupancy state  $O_{jk}$ , as follows:

112 
$$D_{ij} \sim \text{Bernoulli}(p_{ij} * O_{jk})$$

113 where  $p_{ij}$  is the probability of jaguar detection during an occasion (survey) in a site.

114 We estimated both  $\psi$  and  $p$  parameters as linear responses to predictor variables  
115 using a logit link function as performed in a regular logistic model. Then, we added  
116 the line-transect length (values were standardized before running the model) into the  
117 model as a jaguar detection covariate, that is, we expected that the more we walked,  
118 the higher is the likelihood of detecting jaguar signs. We modeled the logit  
119 transformation of detection probability as follows:

120 
$$\text{logit}(p_{ij}) = \alpha_0 + \alpha_1 * \text{transect length}_{ij}$$

121 We also expected that transect length, which was positively correlated with  
122 island size, influences prey species counts. We estimated prey relative abundances ( $\lambda_{lj}$ )  
123 as linear responses to transect length using a log-link function as in a Poisson  
124 regression model as follows:

125 
$$\log(\lambda_{lj}) = \gamma_0 + \gamma_1 * \text{transect length}_j$$

126 where  $\lambda_{lj}$  is the relative abundance of prey species “ $l$ ” (i.e., sloth or howler monkey) in  
127 site “ $j$ ”. Finally, we considered that the occupancy probability  $\psi_{jk}$  depends on the type  
128 of site “ $k$ ” determined by  $\beta_0$  and on the relative abundances of sloths and howlers on  
129 site “ $j$ ” (counts of prey species were centered and scaled before running the model to  
130 compare their coefficients), in a logit transformation of a linear model as follows:

131 
$$\text{logit}(\psi_{jk}) = \beta_0 + \beta_1 * \text{Sloth}_j + \beta_2 * \text{Howler}_j$$

132 The full hierarchical model formulation is presented in Fig. S1. We implemented  
133 the model in a Bayesian framework using JAGS accessed via the software R, version  
134 3.4.1 (R Core Team, 2017) using the package ‘rjags’ (Plummer, 2016) (see the R code  
135 available in Appendix S1). We used flat priors normally distributed with mean = 0  
136 and variance = 100 for all model parameters, except for  $SD$  of  $\beta_0$ , for which we used a  
137 gamma distribution with shape and rate equal to 0.1. The estimation of posterior  
138 parameters was performed with the Markov Chain Monte Carlo (MCMC) method  
139 using three parallel MCMC chains of 100,000 in length after discarding the first 10,000  
140 steps of each as burn-in, and with a thinning rate of 100 steps. This combination of  
141 values ensured that all chains converged, i.e. essentially oscillated around the same  
142 mean parameter value (see Fig. S2) We report the posterior distribution of all  
143 estimated parameters as mean and standard error ( $SE$ ), as well as the median and the

<sup>144</sup> 2.5 and 97.5 percentiles, which are the Bayesian equivalent to the 95% confidence  
<sup>145</sup> interval (highest posterior density in 95% – HPD95).

## <sup>146</sup> Results

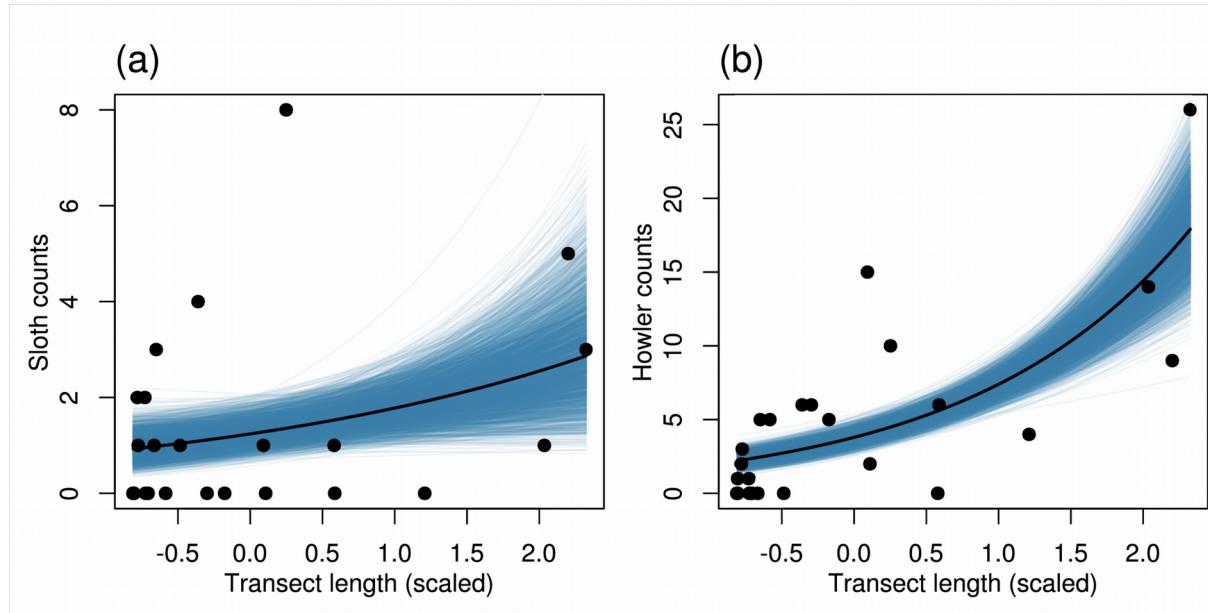

<sup>147</sup> We obtained a total of 20 jaguar independent detections at 15 (63%) of the 24  
<sup>148</sup> sample sites during the four sampling occasions. Counts of both prey species were  
<sup>149</sup> similar in islands and continuous forest (Fig. S3). Sloth counts per transect ranged  
<sup>150</sup> from 0 to 8 individuals. They occurred at 13 (54%) sample sites. Sloth median counts  
<sup>151</sup> per transect were 1 (first quartile (Q1) and third quartile (Q3) = 0 and 2.5,  
<sup>152</sup> respectively) in islands and 0 (Q1 = 0; Q3 = 1) in continuous forest (Fig. S3a). Howler  
<sup>153</sup> counts per transect ranged from 0 to 26 individuals. They inhabited 17 (71%) sample  
<sup>154</sup> sites. The median value of howler counts per transect was 3 individuals (Q1 = 0; Q3 =  
<sup>155</sup> 5.5) in islands and 5 individuals (Q1 = 2; Q3 = 6) in the continuous forest (Fig. S3b).  
<sup>156</sup> The number of sites with predator-prey co-occurrences was 13 (54%) for sites shared  
<sup>157</sup> by jaguars and howlers, and 11 (46%) for jaguars and sloths.

<sup>158</sup> The mean jaguar detection probability across sites was  $p = 0.26$  (HPD95: 0.15–  
<sup>159</sup> 0.39), and it was directly influenced by transect length (Table 1). Transect length was  
<sup>160</sup> also a good predictor of the relative abundance of both prey species (Table 1; Fig. 2).

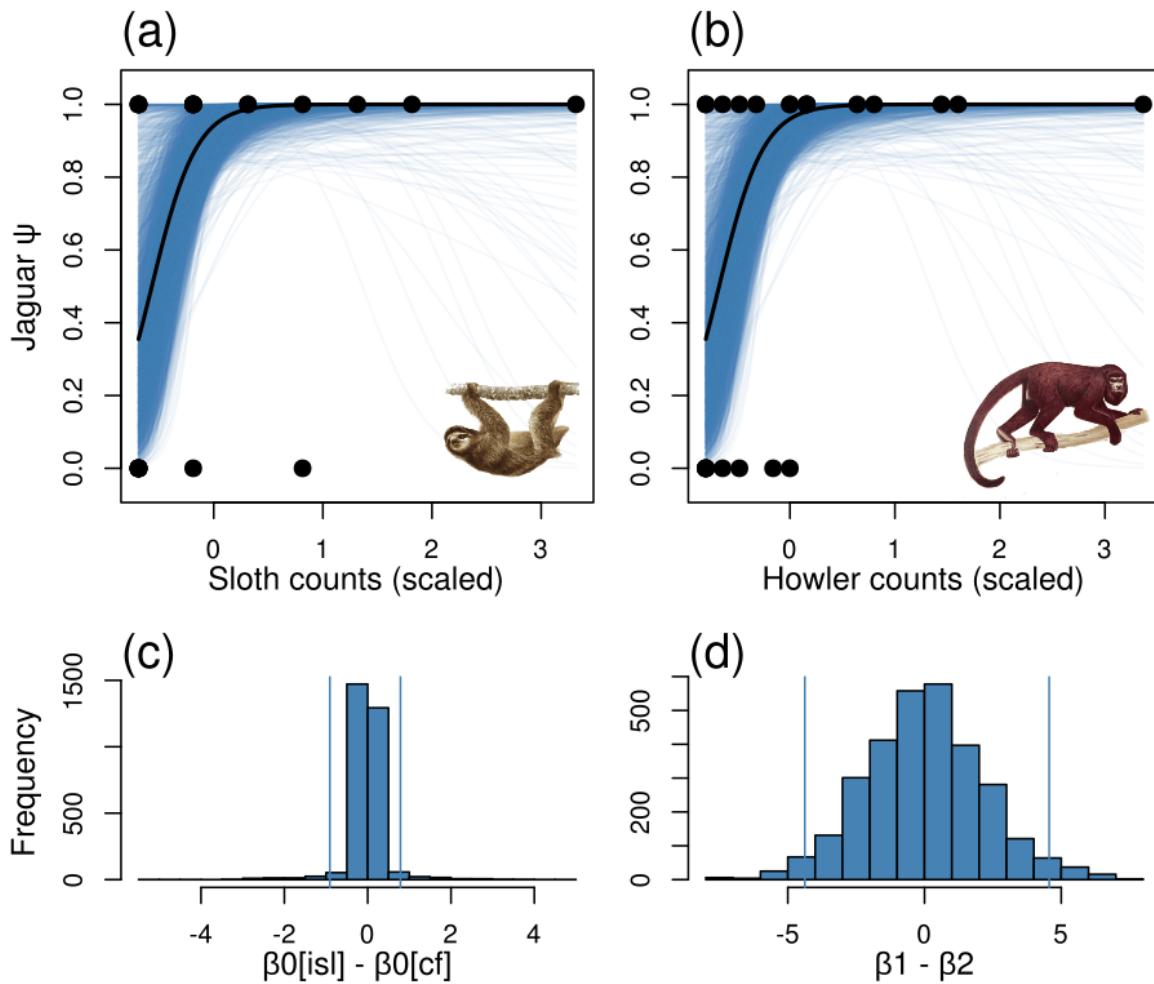

<sup>161</sup> Jaguar probability of site occupancy was positively influenced by the abundance  
<sup>162</sup> of both howlers and sloths (Table 1; Fig. 3a and b). Although both estimates were not  
<sup>163</sup> significant at HPD95 (i.e., the HPD95 interval included the zero), we found strong  
<sup>164</sup> evidence that sloth and howler abundances increase the probability of habitat  
<sup>165</sup> occupancy by jaguars [likelihood estimates:  $p(\beta_1 > 0) = 0.93$  and  $p(\beta_2 > 0) = 0.94$ ,  
<sup>166</sup> respectively]. We estimated a similar proportion of island and continuous forest sites  
<sup>167</sup> used by jaguars ( $\psi = 0.75$ , HPD95: 0.36–1.00, Fig. 3c). Additionally, we found that the  
<sup>168</sup> abundances of both sloths and howlers have similar effects on jaguar probability of  
<sup>169</sup> occurrence ( $\beta_1 - \beta_2 = -0.002$ , HPD95: -4.38–4.56; Fig. 3d).

<sup>170</sup> **Table 1.** Parameter estimates (link scale) from the hierarchical occupancy model for  
<sup>171</sup> jaguar occurrence in Mamirauá's floodplain forest in Central Amazonia.  $\gamma$  and  $\delta$  are  
<sup>172</sup> the coefficients (intercept and slope) of Poisson regressions for the effect of transect  
<sup>173</sup> length on sloths and howlers counts, respectively;  $a$  = coefficients (intercept and  
<sup>174</sup> slope) of logistic model of jaguar detection probability  $p$ ;  $\beta$  = coefficients (intercept  
<sup>175</sup> and slopes) of logistic model of jaguar probability of occurrence  $\psi$ . See full model  
<sup>176</sup> formulation in Fig. S1.

Species	Parameter	Estimate (SE)	2.5%	Median	97.5%
Sloth	$\gamma_0$	0.21 (0.00)	-0.18	0.22	0.58
	$\gamma_1$	0.36 (0.00)	0.06	0.36	0.65
Howler	$\delta_0$	1.33 (0.00)	1.10	1.33	1.54
	$\delta_1$	0.67 (0.00)	0.52	0.67	0.81
Jaguar	$a_0$	-1.05 (0.01)	-1.71	-1.04	-0.43
	$a_1$	0.33 (0.00)	-0.19	0.33	0.85
	$\beta_0$ [islands]	3.27 (0.03)	1.53	2.99	6.72
	$\beta_0$ [cont. forest]	3.26 (0.03)	1.53	2.97	6.70
	$\beta_1$ (sloth)	2.52 (0.03)	-0.66	2.37	6.44
	$\beta_2$ (howler)	2.52 (0.03)	-0.53	2.43	6.06

<sup>177</sup> **Figure 2.** Effects of line-transect length on counts of prey species in Mamirauá's  
<sup>178</sup> floodplain forest in Central Amazonia. Prey counts were used to represent the relative  
<sup>179</sup> local abundances of each species. The longer the walk, the higher the number of  
<sup>180</sup> records of both sloths (a) and howlers (b). The black line represents the median  
<sup>181</sup> exponential response of prey abundance as predicted by a GLM with Poisson  
<sup>182</sup> distribution formulated in a Bayesian framework. Blue lines represent all models  
<sup>183</sup> fitted according to posteriors estimates.

<sup>184</sup> **Figure 3.** Predictors of jaguar occupancy across sample sites in Mamirauá's  
<sup>185</sup> floodplain forest in Central Amazonia. The logit transformation of jaguar probability  
<sup>186</sup> of habitat occupancy ( $\psi$ ) was modelled as a linear function of sample site type (i.e.,  
<sup>187</sup> embedded either in island or in continuous forest), and the abundance of prey species  
<sup>188</sup> at the sample site. Jaguar mean probability of occurrence (black lines) increases  
<sup>189</sup> markedly with increasing abundance of both sloths (a) and howlers (b). Blue lines  
<sup>190</sup> represent all models fitted according to posteriors estimates and higher density of  
<sup>191</sup> lines indicates the area with higher model confidence. There is strong evidence that  
<sup>192</sup> jaguar probability of occurrence does not differ between sites embedded in islands or  
<sup>193</sup> continuous forest, as shown by the distribution of differences between  $\beta_0$  for islands  
<sup>194</sup> and for continuous forest (c). Both sloth ( $\beta_1$ ) and howler ( $\beta_2$ ) counts showed similar  
<sup>195</sup> effects on jaguar probability of habitat use (d).

## 196 Discussion

197 Here we provide the first estimates of jaguar occupancy patterns using sign  
198 surveys along line-transects. We recorded jaguar feces and footprints on trails of  
199 different lengths, accounting for imperfect detection and considering transect length  
200 as a detection covariate. We found a higher average probability of jaguar detection ( $p$   
201 = 0.26) than estimates based on camera trap studies, and a higher probability of  
202 habitat occupancy than most reported estimates (Table 2). Jaguar populations of  
203 Amazonian *várzea* forests have high densities and abundances (Ramalho, 2012),  
204 which allow to expect that they also have high detectability and habitat occupancy.  
205 However, we acknowledge that care needs to be taken in interpreting comparisons  
206 between survey estimates from studies differing in survey method (Table 2) and other  
207 factors (e.g., habitat type and quality, sampling effort, location, etc.). Despite that, we  
208 suggest that sign surveys along line-transects are useful for assessing jaguar  
209 occupancy patterns as they do not require expensive equipment. We urge for such  
210 comparative studies to assess the level of correlation between their estimates.

211 **Table 2.** Comparisons of jaguar mean probabilities of habitat occupancy ( $\psi$ ) and  
212 detection ( $p$ ) among studies.

Survey method	$\psi$	$p$	Location	Reference
Line-transects	0.75	0.26	Mamirauá Reserve, Northern Brazil	This study
Interviews	0.57	0.28	Atlantic Coast, Nicaragua	Zeller et al. (2011)
Camera traps	0.77	0.12	Madre de Dios Department, Peru	Tobler et al. (2015)
	0.69	0.18	Iguaçu National Park, Southern Brazil	Silva et al. (2018)
	0.54	0.21	Emas National Park, Central Brazil	Sollmann et al. (2012)
	0.42	0.26	Magdalena River Valley, Colombia	Boron et al. (2018)
	0.42	0.03	Iwokrama Forest, Guyana	Roopsind et al. (2017)

213 We found no difference in jaguar probability of habitat use between island and  
214 continuous forest samples sites. Jaguars' probability of occurrence tends to be higher  
215 in core areas with high forest cover and close to water (Boron et al., 2018; Silva et al.,  
216 2018; Sollmann et al., 2012; Zeller et al., 2011), and that experience low levels of

<sup>217</sup> anthropogenic disturbance (Roopsind et al. 2017; Silva et al. 2018). Although river  
<sup>218</sup> dynamics constantly changes the spatial structure of Amazonian riverscapes (Peixoto  
<sup>219</sup> et al., 2009), our study *várzea* landscape of Central Amazonia is characterized by high  
<sup>220</sup> forest cover and low human density. Additionally, jaguars move far and easily among  
<sup>221</sup> distinct environments (Morato et al., 2016) and spontaneously cross rivers and lakes  
<sup>222</sup> (Holt, 1932). Therefore, we expect that the aquatic matrix that surrounds fluvial  
<sup>223</sup> islands do not hamper jaguar dispersal across rivers to reach these well-preserved  
<sup>224</sup> island forests.

<sup>225</sup> We found that the relative local abundance of prey species were good predictors  
<sup>226</sup> of jaguar habitat use patterns. Prey density was the best predictor of habitat use by  
<sup>227</sup> tigers (*Panthera tigris*) in a metapopulation also surveyed via signs along trails in  
<sup>228</sup> southern India (Karanth et al., 2011). Likewise, the local occurrence of prey species  
<sup>229</sup> was more important than the distance to water or forest structure to explain jaguar  
<sup>230</sup> habitat use at the Calakmul Biosphere Reserve in southeastern Mexico (Booker, 2016).  
<sup>231</sup> Given that both prey species are equally abundant in islands and continuous forest  
<sup>232</sup> sites (Fig. S3), we suggest that foraging for prey plays a critical role in jaguars'  
<sup>233</sup> decision to use fluvial islands.

<sup>234</sup> We found that both prey species had similar effects on jaguar probability of  
<sup>235</sup> habitat use, despite the lower range of sloth counts per site. Whereas jaguars  
<sup>236</sup> inhabiting non-flooded habitats feed mostly on terrestrial prey (González and Miller,  
<sup>237</sup> 2002), Mamirauá's jaguars rely heavily on caimans and their eggs (Torralvo et al.,  
<sup>238</sup> 2017) and on arboreal mammals (e.g., sloths, howlers and lesser tamanduas  
<sup>239</sup> [*Tamandua tetradactyla*]), as terrestrial prey is often missing in flooded forests  
<sup>240</sup> (Ramalho, 2012). On the other hand, caimans (Da Silveira et al., 2008), sloths and  
<sup>241</sup> howlers (Queiroz, 1995) occur at high densities in these forests, facilitating predator-  
<sup>242</sup> prey encounters. Despite the aforementioned lower abundance of sloths in our flooded  
<sup>243</sup> forests, their solitary life-style and lower mobility and defense ability, make them an  
<sup>244</sup> easy prey, thereby potentially explaining the equal effect of both prey species on  
<sup>245</sup> jaguar habitat use and the importance of sloths to its diet.

<sup>246</sup> In sum, we show that the aquatic matrix surrounding fluvial islands does not  
<sup>247</sup> hamper jaguars to use them. The importance of the abundance of both prey species as  
<sup>248</sup> predictors of jaguar habitat use is compatible with the hypothesis that they often visit  
<sup>249</sup> these islands as part of their prey search strategies. Additionally, we showed that sign  
<sup>250</sup> surveys along trails is an alternative method for assessing the pattern of habitat use  
<sup>251</sup> by jaguars in Amazonian *várzea* forests. Finally, although we conducted this study  
<sup>252</sup> during the low-water season, we believe that the importance of these arboreal

<sup>250</sup> mammals in the diet of jaguars is even higher during the high-water season, when  
<sup>251</sup> jaguars spend most of their time in the forest canopy.

## <sup>252</sup> Acknowledgements

<sup>253</sup> The Instituto de Desenvolvimento Sustentável Mamirauá (IDSM-OS/MCTI) funded  
<sup>254</sup> this research. RMR received fellowships from National Council for Scientific and  
<sup>255</sup> Technological Development (CNPq, #131077/2014-7 and #142352/2017-9). We thank  
<sup>256</sup> the field assistance of Jonei Brasil, André Neves and Jairo Neves. The Infrastructure  
<sup>257</sup> and Logistics and Administration Teams of the Instituto de Desenvolvimento  
<sup>258</sup> Sustentável Mamirauá supported our field activities. We also thank Cristian Dambros  
<sup>259</sup> for providing valuable help on modeling formulation and implementation, Daniel  
<sup>260</sup> Rocha for insightful contributions on the first draft, and two anonymous reviewers  
<sup>261</sup> for their critical evaluation of the manuscript.

## <sup>262</sup> Supporting Information

<sup>263</sup> **Figure S1.** Model formulation.

<sup>264</sup> **Appendix S1.** R code for model implementation.

<sup>265</sup> **Figure S2.** Chain convergence.

<sup>266</sup> **Figure S3.** Prey species counts on island and continuous forest sample sites.
