21

22 **Running title:** bacteria in ovarian tissues.

23

24 **Abstract**

25 The female upper reproductive tract, including the uterus, fallopian tubes and ovaries, is
26 believed to be a sterile environment. With the improvement of bacterial detection, the
27 theory of the sterile female upper reproductive tract has been frequently challenged in
28 recent years. However, thus far, no researchers have used ovaries as study targets. Six
29 women who were diagnosed with ovarian cancer were included in the cancer group, and
30 ten women who were diagnosed with a noncancerous ovarian condition (including three
31 patients with uterine myoma and seven patients with uterine adenomyosis) were included
32 in the control group. Immunohistochemistry staining using an antibacterial
33 lipopolysaccharide (LPS) antibody was used to confirm the presence of bacteria in the
34 ovarian tissues. In addition, 16S rRNA sequencing was used to compare the differences
35 in the bacteria between ovarian cancer tissues and noncancerous ovarian tissues. BugBase
36 and Phylogenetic Investigation of Communities by Reconstruction of Unobserved States
37 (PICRUSt) were used to predict the functional composition of the bacteria. Bacterial LPS
38 was present in ovarian cancer tissue and noncancerous ovarian tissue, which implied the
39 presence of bacteria in ovarian tissue. When compared to the noncancerous ovarian
40 bacteria at the phylum level, the cancerous ovarian bacteria were composed of increased
41 Aquificae and Planctomycetes and decreased Crenarchaeota. When predicting
42 metagenomes, gene functions associated with the potentially pathogenic and the
43 oxidative stress-tolerant phenotype were enriched in the ovaries of the cancer group.
44 Forty-six significantly different KEGG pathways existed in the ovarian bacteria of the
45 cancer group compared to that of the control group. Different bacteria compositions were
46 present in cancerous and noncancerous ovarian tissues.

47

48 **Key words:** ovarian cancer; bacteria; 16S rRNA sequencing

49 **Author summary**

50 Abdominal solid viscera have always been believed to be absolutely sterile. With the
51 improvement of bacterial detection, this concept is being challenged. Researchers found
52 some bacteria existed in endometrial diseases, the question of whether the ovaries are
53 sterile is still unclear. Therefore, we assume that the bacteria in ovarian tissue are
54 associated with ovarian cancer. When compared to the noncancerous ovarian bacteria at
55 the phylum level, the cancerous ovarian bacteria were composed of increased Aquificae
56 and Planctomycetes and decreased Crenarchaeota. When predicting metagenomes, gene
57 functions associated with the potentially pathogenic and the oxidative stress-tolerant
58 phenotype were enriched in the ovaries of the cancer group. Forty-six significantly
59 different KEGG pathways existed in the ovarian bacteria of the cancer group compared to
60 that of the control group. Different bacteria compositions were present in cancerous and
61 noncancerous ovarian tissues.

62

63

64 **Introduction**

65 Abdominal solid viscera, including the pancreas, kidney, spleen, liver and ovary, have
66 always been believed to be absolutely sterile. However, this concept is being challenged.
67 Leore *et al.* found that the bacteria in pancreatic tumors could mediate tumor resistance to
68 the chemotherapeutic drug gemcitabine(1). S. Manfredo Vieira *et al.* confirmed that
69 *Enterococcus gallinarum* can translocate to the lymph nodes, liver and spleen and drive
70 autoimmunity(2).

71 The upper female reproductive tract, including the uterus, fallopian tubes and ovaries,
72 has been believed to be absolutely sterile due to the obstacle of the cervix, which is also
73 being challenged. The change in mucins in the cervix during the menstrual cycle may
74 lead to the passage of bacteria(3, 4). In addition, research has confirmed that the uterus
75 and fallopian tubes represent a functionally united peristaltic pump under the endocrine
76 control of the ovaries(5), which may aid the bacteria to enter the endometrium, fallopian
77 tubes, and ovaries.

78 With the improvement of bacterial detection, researchers have been investigating the
79 upper reproductive tract. Verstraelen *et al.* aimed to explore the presence of a uterine
80 bacteria using a barcoded Illumina paired-end sequencing method targeting the V1-2
81 hypervariable region of the 16S RNA gene(6). Fang *et al.* revealed diverse intrauterine
82 bacterias in patients with endometrial polyps using barcoded sequencing (7). Miles and
83 Chen also investigated the bacteria of the reproductive tract in women undergoing
84 hysterectomy and salpingo-oophorectomy using the 16S RNA gene(4, 8). However, all of
85 the abovementioned researchers used endometrial diseases as their research targets, so the
86 question of whether the ovaries are sterile is still unclear.

87 In recent years, the bacteria of tumor tissues have become a hot topic for researchers.
88 Aleksandar *et al.* confirmed that *Fusobacterium* was enriched in colorectal tumors (9). In
89 addition, Bullman *et al.* discovered that the colonization of human colorectal cancers with
90 *Fusobacterium* is maintained in distal metastases and bacteria stability between paired
91 primary and metastatic tumors(10). Therefore, we assume that the bacteria in ovarian
92 tissue are associated with ovarian cancer.

93

94 In this study, we used immunohistochemistry staining and 16S rRNA sequencing to
95 confirm the presence of bacteria in the ovaries. First, we compared the differences in the
96 ovarian bacteria and its predicted function between cancerous and noncancerous ovarian
97 tissues.

98 **Results**

99 **Participant patients**

100 Sixteen patients who were undergoing oophorectomy or hysterectomy and
101 salpingo-oophorectomy were included in this study. In this study, ten women who were
102 diagnosed with benign endometrial conditions with noncancerous ovaries (including
103 three patients with uterine myoma and seven patients with uterine adenomyosis) were set
104 as the control group, and six women who were diagnosed with ovarian cancer (including
105 two patients who were diagnosed in stage II and four patients who were diagnosed in
106 stage III) were set as the cancer group. All diagnoses were based on final surgical
107 pathology after oophorectomy or hysterectomy and salpingo-oophorectomy. Compared
108 with the control group, the age, menopausal status, parity, history of hypertension and
109 history of diabetes in patients diagnosed with ovarian cancer were not significantly
110 different (**Table 1**).

111 **The presence of bacteria in the ovaries**

112 To confirm the presence of bacteria in ovaries using non-PCR-based methods, we
113 performed immunohistochemistry staining using an antibacterial LPS antibody. The
114 results showed that bacterial LPS were present in the cancerous ovarian tissue and
115 noncancerous ovarian tissue, which implied the presence of bacteria in ovarian tissue
116 (**Fig. 1**).

117 **Ovarian bacterial richness and diversity between the cancer and control groups**

118 To detect the ovarian bacterial species richness and diversity between the two groups, we
119 analyzed the alpha diversity of the microbes. The observed number of species in the
120 ovarian cancer tissues was lower than that in the ovaries of the control group, but the
121 difference was not significant. Moreover, we found that not only the bacterial species
122 richness (represented by the Chao 1 index and the ACE index) but also the diversity
123 (represented by the Shannon Index, the Simpson Index and the Evenness Index) in the
124 ovarian cancer group were not significantly different from those in the control group (**Fig.**
125 **2**).

126 **Ovarian bacteria characterization between the cancer and control groups**

127 To understand the ovarian bacteria in the cancer and control groups, we performed deep
128 sequencing of the V3-V4 16S rRNA region of all sixteen collected samples. In the

129 ovaries, our results showed that Proteobacteria was the most abundant phylum (67.1% in
130 the control group and 67.20% in the cancer group). Firmicutes was the second most
131 abundant phylum (23.77% in the control group and 23.82% in the cancer group), and the
132 third most abundant phylum was Bacteroidetes (3.26% in the control group and 3.41% in
133 the cancer group) (Fig. 2A, 2B). At the species level, the ovarian bacterial communities
134 were dominated by *Halobacteroides halobius* (14.53%), followed by *Gemmata*
135 *obscuriglobus* (11.07%) and *Methyloprofundus sedimenti* (10.69%) in the control group.
136 The ovarian bacterial communities in the cancer group were dominated by *Gemmata*
137 *obscuriglobus* (13.89%), followed by *Halobacteroides halobius* (11.99%) and
138 *Methyloprofundus sedimenti* (11.12%) (Fig. 3).

139 **Ovarian bacterial community composition differences between the cancer and
140 control groups**

141 We carried out a comparison of differences in the overall bacterial communities using
142 PCoA, which showed that the ovarian bacteria of the control group displayed some
143 differences compared to that of the cancer group (Fig. 4A and 4B).

144 **Ovarian bacterial composition at different levels in the cancer and control groups**

145 To detect the differences in ovarian bacteria between the seventeen samples, we analyzed
146 the ovarian bacterial composition at different levels in the cancer and control groups. At
147 the phylum level, the relative abundance of Aquificae and Planctomycetes in the cancer
148 group was higher than that in the control group ($P=0.017$, $P= 0.023$, respectively), and
149 the abundance of Crenarchaeota in the cancer group was lower than that in the control
150 group ($P=0.023$). At the class level, the relative abundance of Spartobacteria sequences
151 was significantly higher in the ovarian communities of the cancer group ($P=0.026$),
152 whereas that of Sphingobacteriia was significantly lower ($P=0.039$). At the genus level,
153 we found that the relative abundance of Pelagicoccus, Haloferula, Volucribacter,
154 Blastococcus and Defluviitoga in the ovarian communities of the cancer group was
155 significantly lower than that of the control group, and the relative abundance of
156 Zavarzinella, Photorhabdus and Mesotoga in the ovarian communities of the control
157 group was significantly lower than that of the cancer group. At the species level, the
158 relative abundance of *Luteolibacter cuticulihirudinis*, *Aureimonas phyllosphaerae*,
159 *Azonexus hydrophilus*, *Anaerostipes rhamnosivorans*, *Calditerricola yamamurai*,

160 *Peptoniphilus methioninivorax*, *Vulcanisaeta thermophile*, a subspecies of
161 *Staphylococcus capitis*, *Mycoplasma genitalium*, *Sulfurospirillum halorespirans*,
162 *Methylomicrobium album*, *Caldicoprobacteroshimai*, *Thermogemmatispora foliorum*,
163 *Mycoplasma equigenitalium*, *Bifidobacterium subtile* and *Rhodopirellula rubra* was
164 significantly higher in the ovarian communities of the ovarian cancer group, whereas the
165 relative abundance of thirty-seven other species was lower than that in the control group
166 (**Table 2**). In particular, the relative abundance of *Anoxynatronum sibiricum* may be
167 associated with the stage of the tumor (**Fig. 4C**), and *Methanoscincus vacuolata* may be
168 used to diagnose ovarian cancer (**Fig. 4D**).

169 **Predicted function of the ovarian bacteria shows phenotypic conservation between
170 the cancer and control groups**

171 BugBase identified that gene functions associated with the potentially pathogenic and the
172 oxidative stress-tolerant phenotype were enriched in the ovaries of the cancer group
173 (Wilcoxon signed-rank test, $P = 0.02$ and $P = 0.002$). The aerobic, anaerobic, facultative
174 anaerobic, gram-positive, and gram-negative phenotypes; mobile elements; and biofilm
175 formation of the ovarian bacteria showed no significant difference between the ovarian
176 cancer and control groups (**Fig. 5**). PICRUSt was used to identify the KEGG pathways
177 between the bacteria of ovaries in the cancer and control groups and found 46 different
178 KEGG pathways. The ovaries in the cancer group showed increased pathways related to
179 streptomycin biosynthesis, carbon fixation in photosynthetic organisms,
180 glycosphingolipid biosynthesis-globo series, cyanoamino acid metabolism,
181 glycerophospholipid metabolism, butirosin and neomycin biosynthesis, other glycan
182 degradation, biosynthesis of vancomycin group antibiotics, polyketide sugar unit
183 biosynthesis, the pentose phosphate pathway, transporters, tuberculosis, starch and
184 sucrose metabolism, fructose and mannose metabolism, phenylalanine metabolism,
185 lysosomes, glycosaminoglycan degradation, pentose and glucuronate interconversions,
186 pyruvate metabolism, amino sugar and nucleotide sugar metabolism, galactose
187 metabolism, biosynthesis of ansamycins, methane metabolism, membrane and
188 intracellular structural molecules, metabolism of cofactors and vitamins, glutamatergic
189 synapse, and the cell cycle. However, the bacteria in ovarian cancer tissue showed
190 reduced alpha-linolenic acid metabolism, biosynthesis of unsaturated fatty acids, bacterial

191 secretion system, proximal tubule bicarbonate reclamation, prion diseases, secretion
192 system, carbon fixation pathways in prokaryotes, unknown functions, other ion-coupled
193 transporters, sulfur metabolism, biotin metabolism, protein kinases, ubiquinone and other
194 terpenoid-quinone biosynthesis, two-component system, folate biosynthesis, cell motility
195 and secretion, citrate cycle (TCA cycle) and ribosome biogenesis in eukaryotes (**Fig. 6**).

196 **Discussion**

197 Ovarian cancer (OC) is the seventh most commonly diagnosed cancer among women that
198 could affect fertility(11). Most ovarian cancer patients are diagnosed at stages III and IV,
199 and the 5-year survival rate is less than 30% (12). Researchers have confirmed that the
200 abdominal solid viscera, including the liver, pancreas and spleen, are not absolutely
201 sterile, and the bacteria exists in the upper female reproductive tract as a result of leakage
202 from the cervix(1, 4). However, the ovaries are still not a research target. The question
203 remains unanswered that whether the ovaries, as one of the abdominal solid viscera, have
204 a bacteria and whether the bacteria has an association with ovarian cancer.

205 In this study, we first confirmed the presence of bacteria in the ovaries. In addition, we
206 detected significant differences in the ovarian bacteria of patients with ovarian cancer
207 when compared with samples from noncancerous women. At the genus level, we found a
208 lower relative abundance of *Pelagicoccus*, *Haloferula*, *Volucribacter*, *Blastococcus* and
209 *Defluviitoga* in ovarian cancer and a higher relative abundance of *Zavarzinella*,
210 *Photorhabdus* and *Mesotoga* in noncancerous ovaries. The genus *Paenibacillus* was
211 previously confirmed to be present in the human body, including in the blood, ascetic
212 fluid, cornea pericardium, and cerebrospinal fluid(13). The genus *Photorhabdus* has been
213 related to soft tissue infection and bacteremia(14). The genus *Dorea* exists in human gut
214 mucosa and tumor tissue and is related to colorectal cancer(15, 16). Another genus was
215 first found present in the human body and had a potential association with ovarian cancer.
216 We predicted ovarian metagenomes and found that the pathogenic and oxidative
217 stress-tolerant phenotype was enriched in the ovaries of the cancer group. Moreover, the
218 enhanced function of cell growth and death in the KEGG pathway was detected in
219 ovarian cancer, which could explain how the bacteria of the ovaries influenced the
220 occurrence and development of the tumor.

221 To avoid bacterial contamination, all instruments used were sterilized, and the reagent
222 we used was new. When operating, the surgeon wore an autoclaved mask, cap and suit
223 and did not talk. The sample did not touch anything in the operating room except for the
224 tweezers and was immediately put into the sterilized tube. When the sample was
225 transferred to the laboratory, as many of the procedures as possible were performed on
226 the asepsis work table except the procedures that required large equipment, such as

227 centrifugal machines and sequencers. More importantly, we used ovaries from patients
228 with benign uterine disease as the control group to counteract possible contamination.

229 There are three possible reasons to explain the origination of the ovarian bacteria. First,
230 a new opinion is that the upper female reproductive tract is not sterile(4), and different
231 bacteria exist throughout the female reproductive tract, forming a continuum from the
232 vagina to the ovaries(12). The bacteria in the ovaries may originate from the
233 fallopian tubes, uterine cavity, cervix canal or vagina, which is in contact with the outside
234 environment. Second, the bacteria in the upper female reproductive tract, including the
235 ovaries, may be endosymbiotic and separated from other bacteria and the outside
236 environment(4). Third, the blood and abdominal cavity may be the potential source of the
237 ovarian bacteria, which is our hypothesis.

238 In this study, we found the presence of bacteria in the ovaries and differences in the
239 ovarian bacteria between patients with ovarian cancer and noncancerous women, which
240 raises further questions that need to be solved. Where did the bacteria originate from?
241 What is the association between the bacteria in the ovaries, uterus, fallopian tubes, vagina,
242 and the outside environment? Are the ovarian bacteria always present? The ovaries are
243 connected and open to the abdominal cavity; did the bacteria transfer from the abdominal
244 cavity and the surface of the organs? Moreover, another doubt is whether the ovarian
245 bacteria is associated with ovulation, ovarian failure, ovarian cysts, polycystic ovarian
246 syndrome and so on. Do the ovarian bacteria drive the occurrence of ovarian cancer or
247 does ovarian cancer change the ovarian bacteria? All of the above questions point to the
248 direction of our future research.

249 There are some limitations to our study. The first limitation is that we could not collect
250 the ovaries from healthy patients for ethical reasons. Therefore, we used the
251 noncancerous ovaries from patients with benign uterine disease (including uterine myoma
252 and adenomyosis) as the control group. Another limitation of this study is the small
253 sample size, which may limit further analysis and influence the accuracy of the results.
254 However, it is the preliminary study to detect the ovarian bacteria in patients with ovarian
255 cancer, and we will conduct further explorations with larger sample sizes.

256 The ovaries contained several kinds of bacteria and were not sterile in a
257 noninflammatory environment. There were significant differences between the ovarian
258 bacterial compositions of patients in the cancer and control groups.
259

260 **Materials and Methods**

261 **Ethics Statement**

262 This study protocol was approved by the Ethics Committee of the First Affiliated
263 Hospital of Xi'an Jiaotong University of China (Approval number:
264 XJTU1AF2018LSK-139). The written informed consents were obtained from all patients
265 participated in the study. All human subjects were adult.

266 **Patient characteristics**

267 Sixteen patients were enrolled at the First Affiliated Hospital of Xi'an Jiaotong University.
268 Patients with any of the following criteria were included in our study: patients
269 undergoing oophorectomy by standard surgical approach and patients undergoing
270 hysterectomy and salpingo-oophorectomy for benign uterine disease (including uterine
271 myoma and uterine adenomyosis) or any stage of ovarian cancer. The exclusion criteria
272 were as follows: patients who were pregnant or nursing, patients who took antibiotics
273 within two months before surgery, and patients who had a fever or elevated inflammatory
274 markers.

275 **Sample collection**

276 Once removed, the ovaries were cut into approximately 1-cm thick ovarian tissue
277 samples using a pair of sterile new tweezers without touching anything else. Then, the
278 collected sample was placed into a sterile tube and placed in liquid nitrogen. Specimens
279 were then transferred to the laboratory and stored at -80°C.

280 **Immunohistochemistry for bacterial lipopolysaccharide (LPS) in ovaries**

281 Immunohistochemistry staining was performed on 5 µm serial sections from routine
282 formalin-fixed, paraffin-embedded (FFPE) tissues. The samples were deparaffinized and
283 rehydrated, and antigen retrieval was performed by microwave treatment for 10 minutes
284 in EDTA buffer (pH 9.0). Endogenous peroxidase activity was stopped by incubating
285 samples with 0.3% hydrogen peroxide in PBS for 20 minutes. A DAB substrate kit was
286 used to detect HRP (Zytomed Systems, Berlin, Germany). A ZyoChem Plus HRP
287 Polymer Anti-Rabbit secondary antibody was used according to the manufacturer's
288 instructions (Zytomed Systems). To find the bacteria, the antibody to LPS core (Hycult
289 Biotech, Uden, Netherlands; Clone WN1 222-5) was used at a concentration of 1:300
290 overnight at 4°C(1).

291 **16S rRNA sequencing**

292 DNA extractions were performed by using the Mag-Bind® Stool DNA 96 Kit (Omega
293 Biotek, Norcross, USA). DNA was quantified using the QuantiFluor dsDNA System
294 (Promega, Madison, USA). The libraries were prepared using an Illumina 16S
295 Metagenomic Sequencing kit (Illumina, Inc., San Diego, USA) according to the
296 manufacturer's protocol. The V3-V4 region of the bacterial 16S rRNA gene sequences
297 was amplified using the primer pair containing the gene-specific sequences and Illumina
298 adapter overhang nucleotide sequences. The full-length primer sequences were as follows:
299 16S Amplicon PCR Forward primer: 5'
300 TCGTCGGCAGCGTCAGATGTGTATAAGAGACAG-[CCTACGGGNGGCWGCAG]
301 and 16S Amplicon PCR Reverse primer: 5'
302 GTCTCGTGGCTCGGAGATGTGTATAAGAGACAG-[GACTACHVGGGTATCTA
303 ATCC].

304 Amplicon polymerase chain reaction (PCR) was performed to amplify the template
305 from the DNA sample input. Briefly, each 25 µL PCR contained 12.5 ng of sample DNA
306 as an input, 12.5 µL of 2x KAPA HiFi HotStart ReadyMix (Kapa Biosystems,
307 Wilmington, USA) and 5 µL of 1 µM of each primer. PCRs were carried out using the
308 following protocol: an initial denaturation step was performed at 95°C for 3 minutes
309 followed by 25 cycles of denaturation (95°C, 30 s), annealing (55°C, 30 s) and extension
310 (72°C, 30 sec), and a final elongation for 5 minutes at 72°C. The reaction mix was
311 removed from the PCR product with Mag-Bind RxnPure Plus magnetic beads (Omega
312 Biotek).

313 A second index PCR amplification, used to incorporate the barcodes and sequencing
314 adapters into the final PCR product, was performed in 25 µL reactions using the same
315 master mix conditions as described above. The cycling conditions were as follows: 95°C
316 for 3 minutes, followed by 8 cycles of 95°C for 30 minutes, 55°C for 30 minutes and
317 72°C for 30 minutes. A final 5-minute elongation step was performed at 72°C.
318 The library was checked using an Agilent 2200 TapeStation and quantified using a
319 QuantiFluor dsDNA System (Promega). Libraries were then normalized, pooled and
320 sequenced (2 x 300 bp paired-end read setting) on the MiSeq (Illumina, San Diego, USA)

321 using a 600 cycle V3 standard flowcell producing approximately 100,000 paired-end
322 2x300 base reads (Omega Bioservices, Norcross, USA).

323 **16S rRNA sequencing analysis**

324 For each sample, the raw reads were filtered based on sequencing quality using
325 Trimmomatic. The primer and adaptor sequences were removed. Sequence reads with
326 both pair end qualities lower than 25 were truncated. The software package QIIME was
327 used to perform the 16S rRNA analyses(2). Sequences were clustered into operational
328 taxonomic units (OTUs) at a 97% similarity cutoff, and the relative abundance was
329 calculated for the OTUs in each sample. All sequences were classified using a native
330 Bayesian classifier trained against the RDP training set (version 9;
331 <http://sourceforge.net/projects/rdp-classifier/>), and OTUs were assigned a classification
332 based on which taxonomy had the majority consensus of the sequences within a given
333 OTU. The OTUs were then aligned to the Silva database. Alpha diversity (including the
334 Chao 1 index, the ACE index, the Shannon index, the Simpson index and the Evenness
335 index) and the UniFrac-based principal coordinates analysis (PCoA) were performed
336 based on the sample group information.

337 **The prediction of bacteria function**

338 The relative representation of the bacteria characteristics was predicted using BugBase on
339 the basis of six phenotype categories (Ward *et al.* unpublished): Gram staining, oxygen
340 tolerance, ability to form biofilms, mobile element content, pathogenicity, and oxidative
341 stress tolerance. This software balances the Kyoto Encyclopedia of Genes and Genomes
342 (KEGG) database, the Integrated Microbial Genomes (IMG4) platform and the
343 Pathosystems Resource Integration Center (PATRIC) system to confirm the contribution
344 of specific OTUs to a community-level phenotype(17-19). PICRUSt was used to predict
345 the functional composition of a metagenome using marker gene data and a database of
346 reference genomes. Functional differences among the different groups were compared
347 using STAMP software (20, 21).

348 **Statistics**

349 Analyses were performed in SPSS unless stated above. $P < 0.05$ was considered an
350 indication of statistical significance. The differences in age and parity of patients were
351 assessed with the use of Student's t test. The differences in menopausal status, history of

352 hypertension and diabetes were assessed using the chi-square test. Differences in the
353 number of ovarian bacteria taxa were assessed with the use of the Mann-Whitney U test.

354

355 **Acknowledgments**

356 We thank the colleagues in the Department of Gynecology of First Affiliated Hospital in
357 Xi'an Jiatong University for their contributions to collecting samples.

441 **Figure legends**

442 **Fig 1. Immunohistochemistry of ovaries using an antibacterial LPS antibody.** A.
443 control group (10x). Scale bars, 200 μ m. B. control group (40x). Scale bars, 50 μ m. C.
444 cancer group (10x). Scale bars, 200 μ m. D. cancer group (40x). Scale bars, 50 μ m.
445 Arrows point to LPS staining in the ovarian tissue.

446 **Fig 2. Bacterial richness and diversity in the cancer and control groups revealed by**
447 **16S rRNA sequencing** A. Observed species index P=0.06; B. Chao 1 index P=0.06; C.
448 ACE index P=0.06; D. Shannon index P=0.32; E. Evenness index P=0.48; F. Simpson
449 index P=0.46.

450 **Fig 3. The relative abundance of phyla (>1%) and the 12 most abundant bacterial**
451 **species in the ovarian samples.** A. The relative abundance of the phyla (>1%) in the
452 ovaries of the patients in the control group. B. The relative abundance of the phyla (>1%)
453 in the ovaries of patients with ovarian cancer. C. The relative abundances of the 12 most
454 abundant bacterial species in the ovaries of the control patients. D. The relative
455 abundances of the 12 most abundant bacterial species in the ovaries of ovarian cancer
456 patients.

457 **Fig 4. Communities clustered using PCoA and the relative abundance of**
458 ***Anoxynatronum sibiricum* and *Methanosarcina vacuolata*.** A. Communities were
459 clustered using PCoA. PC1 and PC2 are plotted on the x and y axes. The red block is
460 equal to a sample in the ovarian cancer group. The blue circle is equal to a sample in the
461 control group. The samples from the ovarian cancer group can be separated from other
462 samples in the control group. B. Communities clustered using Principal Component
463 Analysis (PCoA). PC1 and PC2 are plotted on the x and y axes. The red block is equal to
464 a sample in the ovarian cancer group. The blue solid circle is equal to a sample from a
465 patient with uterine myoma, and the blue hollow circle is equal to a sample of a patient
466 with uterine adenomyosis. C. The relative abundance of *Anoxynatronum sibiricum*. D.
467 The relative abundance of *Methanosarcina vacuolata*.

468 **Fig 5. BugBase analysis of predicted metagenomes.** The potentially pathogenic and
469 oxidative stress-tolerant phenotype of the ovaries in the cancer group was stronger than
470 that of the control group. (Wilcoxon signed-rank test, $P = 0.02$ and $P = 0.002$).

471 **Fig 6. The significantly different KEGG pathways between the cancer and control**
472 **groups by PICRUSt analysis.**

473

Table 1. Clinical characteristics of patients enrolled in the study.

	Control group (n=10)	Cancer group (n=6)	P value
Age	51.6(45-57)	57.3(46-75)	0.29
Menopausal status			0.12
Pre/Peri	8	2	
Post	2	4	
Parity	5.1(1-13)	3.1(2-5)	0.17
History of hypertension			0.52
Yes	1	2	
NO	9	4	
History of diabetes			0.70
Yes	1	1	
NO	9	5	
Stage (%)			
II		2(33.3)	
III		4(66.7)	
Histotype (%)			
Uterine myoma	3(30)	-	
Uterine adenomyosis	7(70)	-	
Ovarian serous carcinoma	-	6(100)	

474

475 **Table 2. Differential relative abundance of the taxa in ovarian communities between patients in cancer and control**
 476 **group.**
