Abstract

The human genome is composed of chromosomal DNA sequences consisting of bases A, C, G and T – the blueprint to implement the molecular functions that are the basis of every individual's life. Deciphering the first human genome was a consortium effort that took more than a decade and considerable cost. With the latest technological advances, determining an individual's entire personal genome with manageable cost and effort has come within reach. Although the benefits of the all-encompassing genetic information that entire genomes provide are manifold, only a small number of *de novo* assembled human genomes have been reported to date ¹⁻³, and few have been complemented with population-based genetic variation ⁴, which is particularly important for North Africans who are not represented in current genome-wide data sets ⁵⁻⁷. Here, we combine long- and short-read whole-genome next-generation sequencing data with recent assembly approaches into the first *de novo* assembly of the genome of an Egyptian individual. The resulting genome assembly demonstrates well-balanced quality metrics and comes with high-quality variant phasing into maternal and paternal haplotypes, which are linked to various gene expression changes in blood. To construct an Egyptian genome reference, we further assayed genome-wide genetic variation

occurring in the Egyptian population within a representative cohort of more than 100 Egyptian individuals. We show that differences in allele frequencies and linkage disequilibrium between Egyptians and Europeans may compromise the transferability of European ancestry-based genetic disease risk and polygenic scores, substantiating the need for multi-ethnic genetic studies and corresponding genome references. The Egyptian genome reference represents a comprehensive population data set based on a high-quality personal genome. It is a proof of concept to be considered by the many national and international genome initiatives underway. More importantly, we anticipate that the Egyptian genome reference will be a valuable resource for precision medicine targeting the Egyptian population and beyond.

Main

With the advent of personal genomics, population-based genetics as part of an individual's genome is indispensable for precision medicine. Currently, genomics-based precision medicine compares the patients' genetic make-up to a reference genome⁹, a genome model inferred from individuals of mostly European descent, to detect risk mutations that are related to disease. However, genetic and epidemiologic studies have long recognized the importance of ancestral origin in conferring genetic risk for disease. Risk alleles and structural variants (SVs)¹⁰ can be missing from the reference genome or can have different population frequencies, such that alternative pathways become disease related in patients of different ancestral origin, which motivates the establishment of national or international multi-ethnic genome projects^{6,7,11}. At present, there are several population-based sequencing efforts that aim to map specific variants in the 100,000 genome projects in Asia¹² or England¹³. Furthermore, large-scale sequencing efforts currently explore population, society and history-specific genomic variations in individuals in Northern and Central Europe^{14,15}, North

America ⁷, Asia ^{16,17} and, recently, the first sub-Saharan Africans ^{18,19}. Nonetheless, there is still little genetic data available for many regions of the world. In particular, North African individuals are not adequately represented in current genetic data sets, such as the 1000 Genomes ⁵, TOPMED ⁷ or gnomAD ⁶ databases. Consequently, imminent health disparities between different world populations have been noted repeatedly for a decade. ^{20–23}

In recent years, several high-quality *de novo* human genome assemblies ^{1–4} and, more recently, pan-genomes ⁸ have extended human sequence information and improved the *de facto* reference genome GRCh38 ⁹. Nonetheless, it is still prohibitively expensive to obtain all-embracing genetic information, such as high-quality *de novo* assembled personal genomes for many individuals. Indeed, previous genetic studies assess only a subset of variants occurring in the Egyptian population, e.g., single nucleotide polymorphisms (SNPs) on genotyping arrays ^{24,25}, variants in exonic regions via exome sequencing ²⁶ or variants detectable by short-read sequencing ^{27,28}.

In this study, we generated a phased *de novo* assembly of an Egyptian individual and identified single nucleotide variants (SNVs) and SVs from an additional 109 Egyptian individuals obtained from short-read sequencing. Those were integrated to generate an Egyptian genome reference. We anticipate that an Egyptian population genome reference will strengthen precision medicine efforts that eventually benefit nearly 100 million Egyptians, e.g., by providing allele frequencies (AFs) and linkage disequilibrium (LD) between variants, information that is necessary for both rare and common disease studies. Likewise, our genome will be of universal value for research purposes, since it contains both European and African variant features. Most genome-wide association studies (GWAS) are performed in Europeans ²⁹, but genetic disease risk may differ, especially for individuals of African ancestry ³⁰. Consequently, an Egyptian genome reference will be well suited to support recent

efforts to include Africans in such genetic studies, for example, by serving as a benchmark data set for SNP array construction and variant imputation or for fine-mapping of disease loci.

Our Egyptian genome is based on a high-quality human *de novo* assembly for one Egyptian individual (see workflow in Suppl. Fig. 1). This assembly was generated from PacBio, 10x Genomics and Illumina paired-end sequencing data at overall 270x genome coverage (Suppl. Table 1). For this personal genome, we constructed two draft assemblies, one based on long-read assembly by an established assembler, FALCON³¹, and another based on the assembly by a novel assembler, WTDBG2³², which has a much shorter run time with comparable accuracy (cf. Suppl. Fig. 1). Both assemblies were polished using short reads and various polishing tools. For the FALCON-based assembly, scaffolding was performed, whereas we found that the WTDBG2-based assembly was of comparable accuracy without scaffolding (cf. dot plots in Suppl. Figs. 3-4). The WTDBG2-based assembly was selected as the base because it performs comparable or better according to various quality control (QC) measures (Suppl. Table 2). Where larger gaps outside centromere regions occurred, we complemented this assembly with sequence from the FALCON-based assembly (Suppl. Table 3) to obtain a final Egyptian meta-assembly, denoted as EGYPT (for overall assembly strategy, see Suppl. Fig. 1). We found our assembly to be comparable to the publicly available assemblies of a Korean³³ and a Yoruba individual (GenBank assembly accession GCA_001524155.4, unpublished) with respect to various QC measures³⁴ (Table 1). Suppl. Fig. 2 compares the assemblies' NA-values, and Suppl. Figs. 3-7 show dot plots of alignment with reference GRCh38. We performed repeat annotation and repeat masking for all assemblies (Suppl. Table 4).

The meta-assembly was complemented with high-quality phasing information (Suppl. Table 5). EGYPT SNVs and small insertions and deletions (indels) called using short-read sequencing data were phased using high-coverage 10x linked-read sequencing data. This

resulted in 98.99% of variants being phased. Furthermore, nearly all (99.41%) of the genes with lengths less than 100 kb and more than one heterozygous SNP were phased into a single phase block.

Based on the personal Egyptian genome, we constructed an Egyptian population genome by considering genome-wide SNV AFs in 109 additional Egyptians (Suppl. Table 6). This approach enabled the characterization of the major allele (i.e., the allele with highest AF) in the given Egyptian cohort. To accomplish this, we called variants using short-read data of 13 Egyptians sequenced at high coverage and 97 Egyptians sequenced at low coverage. Although sequence coverage affects variant-based statistics (Suppl. Fig. 8), due to combined genotyping, most variants could also be called reliably in low coverage samples (Suppl. Fig. 9). Altogether, we called a total of 19,758,992 SNVs and small indels (Suppl. Fig. 10) in all 110 Egyptian individuals (Fig. 1). The number of called variants per individual varied between 2,901,883 to 3,934,367 and was correlated with sequencing depth (see Suppl. Figs. 8-9). This relationship was particularly pronounced for low coverage samples. The majority of variants were intergenic (53.5%) or intronic (37.2%) (Suppl. Fig. 11). Only approximately 0.7% of the variants were located within coding exons, of which 54.4% were non-synonymous and thus cause a change in protein sequence and possibly structure (Suppl. Fig. 12).

Using short-read sequencing data of 110 Egyptians, we called 121,141 SVs, most of which were deletions but also included inversions, duplications, insertions and translocations of various orders of magnitude (Fig. 1, Suppl. Fig. 13-14). Similar to SNVs, the number of SV calls also varied between individuals (Suppl. Fig. 15) and is slightly affected by coverage (Suppl. Fig. 16). After merging overlapping SV calls, we obtained an average of 2,773 SVs per Egyptian individual (Suppl. Table 7, Suppl. Figs. 17-19).

130

131 To characterize the Egyptian population with respect to European and African populations
132 that have been genotyped within the 1000 Genomes Project ⁵ (Suppl. Table 8), we used SNVs
133 and short indels for a genotype-based principal component analysis. According to this
134 analysis, Egyptians are a genetically homogenous population compared to other populations,
135 sharing genetic components with both Europeans and sub-Saharan Africans (see Fig. 2 and
136 Suppl. Figs. 20-32). Thus far, there are no North African populations with high-quality
137 whole-genome sequencing-based genotype data available, and in the European and sub-
138 Saharan African populations reported by the 1000 Genomes Project, Egyptians are closest to
139 the European Tuscany population (see Fig. 2 and Suppl. Figs. 20-32), which has been
140 previously proposed through genetic studies of ancient Egyptian mummies ³⁵.

141

142 The mixed European and African ancestry of Egyptians is further supported by mitochondrial
143 haplogroup assessment from the literature ²⁷ and our own mtDNA sequencing data (overall
144 n=327). We found that Egyptians have haplogroups most frequently found in Europeans (e.g.,
145 H, V, T, J, etc.; more than 60%), and many Egyptians also have African (e.g., L with 24.8%)
146 or Asian/East Asian haplogroups (e.g., M with 6.7%). This indicates that Egyptian genomes
147 contain genetic components from various major human populations (Suppl. Fig. 33), as has
148 been shown recently for a few Egyptian individuals in a study that performed genome-wide
149 admixture analysis of populations from the Arabian Peninsula using SNP arrays ²⁵.

150

151 In total, we identified 6,599,037 common Egyptian SNVs (minor allele frequency (MAF) >
152 5%, genotypes in a minimum of 100 individuals), of which 1,198 are population-specific; i.e.,
153 they are either rare (MAF < 1%) or not detected in any other population in the 1000 Genomes
154 ⁵ and gnomAD databases ⁶ as well as TOPMed ⁷ (Suppl. Table 9). These numbers are
155 comparable to population-specific variant numbers reported previously for 1000 Genomes

populations³⁶. Four SNVs likely have a molecular impact (Suppl. Table 10), indicated by a CADD³⁷ deleteriousness score greater than 20. SNP rs143563851 (CADD 24.2) has recently been identified in 1% of individuals of a cohort of 211 Palestinians in a study that performed targeted sequencing of blood group antigen synthase GBGT1³⁸. SNP rs143614333 (missense variant in gene CR2, CADD 23.6) is in ClinVar³⁹, with three submitters reporting that the variant is of uncertain clinical significance. Additionally, we obtained 49 variants with no dbSNP⁴⁰ rsID (Suppl. Table 11). These numbers of population-specific SNPs, of which some likely have an immediate impact on clinical characteristics and diagnostics, indicate insufficient coverage of the genetic diversity of the world's population for precision medicine and thus the need for local genome references. To detect a putative genetic contribution of Egyptian population-specific SNPs towards molecular pathways, phenotypes or disease, we performed gene set enrichment analysis for all 461 protein-coding genes that were annotated to population-specific SNPs by Ensembl VEP⁴¹. Enrichr, a gene list enrichment tool incorporating 153 gene sets and pathway databases⁴², reports that genes from obesity-related traits of the GWAS catalog 2019 collection are over-represented (adj. p-value: 1.02E-6; 49 of 804 genes), which might hint at population-specific metabolism regulation that is linked to body weight.

173

Variants that are not protein coding may have a regulatory effect that affects gene and eventually protein expression. Using blood expression data obtained from RNA sequencing for the EGYPT assembly individual in conjunction with 10x sequencing-based phased variant data, we identified genes whose expression differs between maternal and paternal haplotypes (see Suppl. Fig. 34 for the analysis overview and Suppl. Figs. 35-36 for the results). We report 1,180 such genes (Suppl. Table 12). Of these, variants contained in haplotypes of 683 genes (58%) have previously reported expression quantitative trait loci (eQTLs) in blood according to Qtlizer⁴³, for 380 genes supported by multiple studies. For 370 genes (31%), the

strongest associated blood eQTL SNV is haplotypically expressed, and for 131 genes, the best eQTL has been previously reported by multiple studies. Concordance of haplotypic expression with eQTLs indicates that a common variant may affect gene expression; discordance hints towards a rare variant.

We investigated the impact of Egyptian ancestry on disease risk by integrating Egyptian variant data with the GWAS catalog⁴⁴, a curated database of GWAS. According to the GWAS catalog, most published GWAS are performed in Europeans²⁹, and only a single study has been performed in Egyptians⁴⁵ (by one of our groups). Furthermore, only 2% of individuals included in GWAS are of African ancestry²⁹. AFs, LD and genetic architecture can differ between populations, such that results from European GWAS cannot necessarily be transferred³⁰. This lack of transferability also compromises the prediction of an individual's traits and disease risk using polygenic scores: such scores are estimated to be approximately one-third as informative in African individuals compared to Europeans⁴⁶. From the GWAS catalog, we constructed a set of 4,008 different, replicated, high-quality tag SNPs (i.e., one strongest associated SNP per locus) from European ancestry GWAS for 584 traits and diseases. We compared the tag SNPs' AFs and proxy SNPs in the Egyptian cohort (n=110) and Europeans from 1000 Genomes (n=503) (Suppl. Table 13). Egyptian AFs of tag SNPs are comparable to European AFs, with a tendency to be lower (Fig. 3a). There are variants common in Europeans (AF>5%) but rare in Egyptians (AF<5%) (Suppl. Fig. 37). A total of 261 tag SNPs are not present in the Egyptian cohort (~7%), clearly indicating a need to perform GWAS in non-European populations to further elucidate disease risk conferred by these loci. We investigated differences in LD structure using an approach that is used for fine-mapping of GWAS data, which identifies proxy variants (illustrated in Fig. 3c). Proxy variants are variants correlated with the tag GWAS SNP, i.e., in high LD (here, $R^2>0.8$). The post-GWAS challenge is the identification of a causal variant from a set of variants in LD (tag

SNP and proxy variants). We found that the number of proxy variants was much lower in the Egyptian cohort (Fig. 3b), likely due to shorter haplotype blocks known from African populations. This indicates that LD differences between Egyptians and Europeans may compromise GWAS transferability and European ancestry-based polygenic scores. However, Egyptian proxy variants are usually included in the larger set of European proxy variants (Fig. 3d). An example is variant rs2075650 (a locus sometimes attributed to gene TOMM40), which has been linked to Alzheimer's disease in seven GWASs (cf. Suppl. Fig. 38). This tag SNP has seven proxy variants in Europeans but only two proxy variants in Egyptians. One European proxy, rs72352238, has also been reported as a GWAS tag SNP, but it is not a proxy of rs2075650 in Egyptians and may thus fail replication and transfer of GWAS results from the European to the Egyptian population.

With our Egyptian genome reference, it will be possible to perform comprehensive integrated genome and transcriptome comparisons for Egyptian individuals and shed light on personal as well as population-wide common genetic variants. Fig. 4 visualizes the various types of data of this resource in the integrative genomics viewer ⁴⁷ (IGV). Here, we selected the DNA repair-associated gene BRCA2, which, if mutated, is linked to breast cancer and other cancer types ⁴⁸. IGV depicts the sample coverage based on sequencing data from PacBio, 10x Genomics and Illumina (whole genome as well as RNA) for the personal EGYPT genome together with common Egyptian SNPs. Variants previously assessed in a breast cancer GWAS ⁴⁸ are displayed as Manhattan plot; note the three significant GWAS SNPs between positions 32,390 and 32,400 kb. The bottom compares the identified SNVs and indels from the Korean and Yoruba *de novo* assembly with our *de novo* EGYPT assembly. Visual inspection already yields significantly different variants. This integrative view sheds light on both small and structural variations at the personal and population-based genome levels.

In conclusion, we constructed the first Egyptian – and North African – genome reference, which is an essential step towards a comprehensive, genome-wide knowledge base of the world’s genetic variations. The wealth of information it provides can be immediately utilized to study in-depth personal genomics and common Egyptian genetics and its impact on molecular phenotypes and disease. This reference will pave the way towards a better understanding of the Egyptian, African and global genomic landscape for precision medicine.

Methods

Sample acquisition

Samples were acquired from 10 Egyptian individuals. For nine individuals, high-coverage Illumina short-read data were generated. For the assembly individual, high-coverage short-read data were generated as well as high-coverage PacBio data and 10x data. Furthermore, we used public Illumina short-read data from 100 Egyptian individuals from Pagani *et al.* ²⁷. See Supplementary Tables 1 and 6 for an overview of the individuals and the corresponding raw and result data generated in this study.

PacBio data generation

For PacBio library preparation, the SMRTbell DNA libraries were constructed following the manufacturer’s instructions (Pacific Bioscience, www.pacb.com). The SMRTbell DNA libraries were sequenced on the PacBio Sequel and generated 298.2 GB of data.

Sequencing data from five PacBio libraries were generated at overall 99x genome coverage.

Illumina short-read data generation

For 350 bp library construction, the genomic DNA was sheared, and fragments with sizes of approximately 350 bp were purified from agarose gels. The fragments were ligated to

adaptors and amplified using PCR. The generated libraries were then sequenced on the Illumina HiSeq X Ten using PE150 and generated 312.8 GB of data.

For the assembly individual, sequencing data from five libraries was generated at overall 90x genome coverage. For nine additional individuals, one library each was generated, amounting to an overall 305x coverage of sequencing data. For the 100 individuals of Pagani *et al.*²⁷, three were sequenced at high coverage (30x) and 97 at low coverage (8x). The average coverage over SNV positions for all 110 samples is provided in Supplementary Table 6.

RNA sequencing data generation

For RNA sequencing, ribosomal RNA was removed from total RNA, double-stranded cDNA was synthesized, and then adaptors were ligated. The second strand of cDNA was then degraded to generate a directional library. The generated libraries with insert sizes of 250-300 bp were selected and amplified and then sequenced on the Illumina HiSeq using PE150. Overall, 64,875,631 150 bp paired-end sequencing reads were generated.

10x sequencing data generation

For 10x genomic sequencing, the Chromium Controller was used for DNA indexing and barcoding according to the manufacturer's instructions (10x Genomics, www.10xgenomics.com). The generated fragments were sheared, and then adaptors were ligated. The generated libraries were sequenced on the Illumina HiSeq X Ten using PE150 and generated 272.7 GB of data. Sequencing data from four 10x libraries was generated at overall 80x genome coverage.

Construction of draft *de novo* assemblies and meta-assembly

We used WTDBG2³² for human *de novo* assembly followed by its accompanying polishing tool WTPOA-CNS with PacBio reads and in a subsequent polishing run with Illumina short

reads. This assembly was further polished using PILON⁴⁹ with short-read data (cf. Suppl. Methods: *WTDBG2-based assembly*).

An alternative assembly was generated by using FALCON⁵⁰, QUIVER⁵¹, SSPACE-LONGREAD⁵², PBJELLY⁵³, FRAGSCAFF⁵⁴ and PILON⁴⁹ (cf. Suppl. Methods: *FALCON-based assembly*).

Proceeding from the WTDBG2-based assembly, we constructed a meta-assembly. Regions larger than 800 kb that were not covered by this base assembly and were not located within centromere regions were extracted from the alternative FALCON-based assembly (Suppl. Table 3). See Suppl. Fig. 1 for an overview of our assembly strategy, including meta-assembly construction (cf. Suppl. Methods: *Meta-assembly construction*).

Assembly quality and characteristics were assessed with QUAST-LG⁵⁵ (cf. Suppl. Methods: *Assembly comparison and QC*). The extraction of coordinates for meta-assembly construction was performed using QUAST-LG output.

Repeatmasking

Repeatmasking was performed by using REPEATMASKER⁵⁶ with RepBase version 3.0 (Repeatmasker Edition 20181026) and Dfam_consensus (<http://www.dfam-consensus.org>) (cf. Suppl. Methods: *Repeat annotation*).

Phasing

Phasing was performed for the assembly individual's SNVs and short indels obtained from combined genotyping with the other Egyptian individuals, i.e., based on short-read data. These variants were phased using 10x data and the 10x Genomics LONGRANGER WGS pipeline with four 10x libraries provided for one combined phasing. See Supplementary Methods *Variant phasing* for details.

SNVs and small indels

Calling of SNVs and small indels was performed with GATK 3.8⁵⁷ using the parameters of the best practice workflow. Reads in each read group were trimmed using Trimmomatic⁵⁸ and subsequently mapped against reference genome hg38 using BWA-MEM⁵⁹ version 0.7.17. Then, the alignments for all read groups were merged sample-wise and marked for duplicates. After the base recalibration, we performed variant calling using HaplotypeCaller to obtain GVCF files. These files were input into GenotypeGVCFs to perform joint genotyping. Finally, the variants in the outputted VCF file were recalibrated, and only those variants that were flagged as “PASS” were kept for further analyses. We used FastQC⁶⁰, Picard Tools⁶¹ and verifyBamId⁶² for QC (cf. Suppl. Methods: *Small variant QC*).

Variant annotation

Variant annotation was performed using ANNOVAR⁶³ and VEP⁴¹ (cf. Suppl. Methods: *Small variant annotation*)

Structural variants

SVs were called using DELLY2⁶⁴ with default parameters as described on the DELLY2 website for germline SV calling (<https://github.com/dellytools/delly>) (cf. Suppl. Methods: *Structural variant QC*). Overlapping SV calls in the same individual were collapsed by the use of custom scripts. See Supplementary Methods *Collapsing structural variants* for details.

Genotype-based principal components

1000 Genomes phase 3 variant data were obtained for all European and African individuals and merged with the Egyptian variant data. Variants were excluded if their MAF was less than 5% among individuals in the 1000 Genomes database, they violated Hardy-Weinberg equilibrium, or they were multi-allelic or within regions of high LD and/or of known

inversions. LD pruning was performed, and the remaining SNPs passed on to the SMARTPCA program⁶⁵ of the EIGENSOFT package for PC computation. See Supplementary Methods *Genotype-based principal components* for details.

Mitochondrial haplogroups

Haplogroup assignment was performed for 227 individuals using HAPLOGREP 2⁶⁶. Furthermore, mitochondrial haplogroups were obtained from Pagani *et al.*²⁷ for 100 individuals. See Supplementary Methods *Mitochondrial haplogroups* for details.

Population-specific variants

Our set of common Egyptian SNVs comprises variants with genotypes in a minimum of 100 individuals whose alternative allele has a frequency of more than 5%. Those common Egyptian SNVs that are otherwise rare, i.e., have an AF of less than 1% in the 1000 Genomes, and gnomAD populations as well as in TOPMed were considered Egyptian-specific. AFs were annotated using the Ensembl API. Furthermore, a list of Egyptian common variants without dbSNP rsID was compiled, see Supplementary Methods *Small variant annotation* for details.

Haplotypic expression analysis

RNA sequencing reads were mapped and quantified using STAR (Version 2.6.1.c)⁶⁷. Haplotypic expression analysis was performed by using PHASER and PHASER GENE AE (version 1.1.1)⁶⁸ with Ensembl version 95 annotation on the 10x-phased haplotypes using default parameters. See Supplementary Methods *Haplotypic expression* for details.

GWAS catalog data integration

GWAS catalog associations for GWAS of European ancestry were split into trait-specific data sets using Experimental Factor Ontology (EFO) terms. For every trait, a locus was defined as an associated variant +/- 1 MB, and only loci that were replicated were retained. For proxy computation, we used our Egyptian cohort (n=110) and the European individuals of 1000 Genomes (n=503). For details, see Supplementary Methods *Data integration with the GWAS catalog*.

Integrative genomics view

We implemented a workflow to extract all Egyptian genome reference data for view in the IGV⁴⁷. This includes all sequencing data mapped to GRCh38 (cf. Suppl. Methods *Sequencing read mapping to GRCh38*) as well as all assembly differences (cf. Suppl. Methods *Alignment to GRCh38 and Assembly-based variant identification*) and all Egyptian variant data. See Supplementary Methods *Gene-centric integrative data views* for details.

Ethics statement

This study was approved by the Mansoura Faculty of Medicine Institutional Review Board (MFM-IRB) Approval Number RP/15.06.62. All subjects gave written informed consent in accordance with the Declaration of Helsinki. This study and its results are in accordance with the Jena Declaration (https://www.uni-jena.de/unijenamedia/Universitaet/Abteilung+Hochschulkommunikation/Presse/Jenaer+Erklaerung/Jenaer_Erklaerung_EN.pdf).

Acknowledgements

We acknowledge support on coordination of the project and assembly work w.r.t the FALCON-based assembly through Ms. Lu Wang from the Novogene (UK) Company Limited. HB and IW acknowledge funding by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy – EXC 22167-390884018. All authors acknowledge computational support from the OMICS compute cluster at the University of Lübeck.

Contributions

H.B, S.I. and M.S. conceived the study. I.W, A.K, M.M., H.B. and S.I. designed the study. I.W., A.K., M.M., M.O and A.F. performed data analysis. C.M. constructed the FALCON-based assembly. M.S. and S.E-M. compiled the Egyptian cohort and provided samples. M.H. performed mtDNA library preparation and sequencing. I.W., H.B. and S.I. wrote the manuscript. All authors read and approved the final manuscript.

Competing interests

The authors declare no competing interests.

Data availability

All summary data of the Egyptian genome reference are available at www.egyptian-genome.org. The Egyptian genome reference will be publicly available upon journal publication.

Code availability

Computational tools and parameters used are specified in the Supplementary Methods. Workflows have been implemented to permit reproducible data analyses by using Snakemake as workflow management system, Git for version control of workflow code and Conda (especially Bioconda) for managing software environments.
