Abstract

An obligately anaerobic, non-motile, Gram-positive coccobacillus strain SW451 was isolated from pooled cecum contents of feral chickens. Comparative analysis based on 16S rRNA sequence showed that strain SW451 had 95.24% nucleotide sequence similarity to *Sellimonas intestinalis* BR31^T, the closest species with a valid taxonomy. The genome of SW451 is 2.67 Mbp with 45.23 mol% of G+C content. The major cellular fatty acids were C_{16:0}, C_{14:0} and C_{16:0} DMA. Based on taxonogenomic, physiological, and biochemical analysis, the strain SW451 represents a new species of the genus *Sellimonas*, for which the name *Sellimonas caecigallum* sp. nov. is proposed. The type strain of *Sellimonas caecigallum* is SW451 (=DSM 109473^T)

Introduction

The chicken gut contains a diverse microbial community which is dominated by the phyla Firmicutes, Actinobacteria, Proteobacteria and Bacteroidetes (1-3). Gut commensal bacteria play an important role in host metabolism, immune system and pathogen protection (4, 5). Recently, gut microbiota has been studied using culture-independent and culture-dependent techniques. Sequencing-based analysis of the gut microbiome is useful for identifying dynamic changes in microbiota composition, while culturing is used to access biological functions of individual microbiota members and their interactions (6-8). However, the cultivation and isolation of several bacterial species from gut microbiota remains a daunting problem. Here, we report the cultivation and characterization of a new bacterial species from the cecum of feral chicken. The proposed *Sellimonas caecigallum* sp. nov. strain SW451 (=DSM 109473) is a new member of genus *Sellimonas*.

Isolation, growth conditions and strain identification

Strain SW451 was isolated from cecum of feral chicken by culturing in strict anaerobic conditions in a Coy Lab anaerobic chamber containing 85% nitrogen, 10% hydrogen and 5% carbon dioxide. Modified Brain Heart Infusion (BHI-M) medium, which contained 37 g/L of BHI, 5 g/L of yeast extract, 1 ml of 1 mg/mL menadione, 0.3 g of L-cysteine, 1 mL of 0.25 mg/L of resazurin, 1 mL of 0.5 mg/mL hemin, 10 mL of vitamin and mineral mixture, 1.7 mL of 30 mM acetic acid, 2 mL of 8 mM propionic acid, 2 mL of 4 mM butyric acid, 100 µl of 1 mM isovaleric acid, and 1% of pectin and inulin was used for strain culturing and maintenance. Genomic DNA of the strain SW451 was extracted using DNeasy Blood & Tissue kit (Qiagen), according to the manufacturer's instructions. 16S rRNA gene sequences was amplified using universal primer set 27F (5'-AGAGTTTGATCMTGGCTCAG-3') and 1492R (5'-ACCTTGTTACGACTT-3') (9, 10). The PCR amplicon was sequenced using Sanger dideoxy method (ABI 3730XL; Applied Biosystems). The 16S rRNA gene sequence of SW451 was compared to closely related strains obtained from the GenBank (www.ncbi.nlm.nih.gov/genbank/) and EZtaxon databases (www.ezbiocloud.net/eztaxon) (11). Phylogenetic analysis was conducted using MEGA7 software (12). Multiple alignments were generated using the CLUSTAL-W algorithm (13). Reconstruction of phylogenetic trees was carried out using the maximum-likelihood (ML) (14), maximum-parsimony (MP) (15), and neighbour-joining

(NJ) (16) methods. The distance matrices were generated using Kimura's two-parameter model. Bootstrap resampling analysis of 1000 replicates was performed to estimate the confidence of tree topologies. Based on the results of 16S rRNA gene sequencing, the closest taxa of SW451 were *Sellimonas intestinalis* DSM 103502^T (95.24% similarity) and *Clostridium nexile* KCTC 5578^T (94.47%), followed by *Merdimonas faecis* KCTC 15482^T (94.34%) and *Faecalimonas umbilicata* DSM 103426^T (94.08%). The results of phylogenetic analysis showed that SW451 was clustered with the *Sellimonas* clade and it represents a new member of the genus *Sellimonas* (Fig. 1).

Genome properties and comparison

The whole genome sequencing of strain SW451 was performed using Illumina MiSeq sequencer with Illumina V3 2 x 250 chemistry. The reads were assembled using Unicycler that builds an initial assembly graph from short reads using the *de novo* assembler SPAdes 3.11.1 (17). The quality assessment for the assembly was performed using QUAST (18). The draft genome of strain SW451 has total length of 2.67 Mbp. The genomic G+C content of SW451 was 45.13 mol%. Genome features of the strain was distinct from other related strains (Table 3). In addition, the average nucleotide identity (ANI) was calculated between SW451 and the closest related strains using OrthoANI software (19). The ANI values were significantly less than the proposed ANI cutoff of 95–96% (20), demonstrating strain SW451 as a novel species (Fig. 2).

Phenotypic characteristics

Colony morphology of strain SW451 was determined after 2-3 days of incubation on BHI-M agar plates. Gram-staining was performed using a Gram-Staining kit set (Difco), according to the manufacturer's instructions. Cell morphologies of cultures during exponential growth were examined by scanning electron microscopy (SEM). Aerotolerance was examined by incubating cultures for 2 days under aerobic and anaerobic conditions. Growth of strain SW451 at 4, 20, 30, 37, 40 and 55° C was determined. For pH range, the pH of the medium was adjusted to pH 4–9 with sterile anaerobic solutions of 0.1 M HCl and 0.1 M NaOH. Motility of this microorganism was determined using motility medium with triphenyltetrazolium chloride (TTC) (21). The growth was indicated by the

presence of red color, reduced form of TTC after it is absorbed into bacterial cell wall. Other biochemical tests including utilization of various substrates and enzyme activities were determined using the AN MicroPlate (Biolog) and API ZYM (bioMérieux) according to the manufacturer's instructions. For cellular fatty acid analysis, strain SW451 was cultured in BHI-M medium at 37°C for 24 h under anaerobic condition. Cellular fatty acids were obtained from cell biomass and analyzed by GC (Agilent 7890A) according to the manufacturer's instruction of Microbial Identification System (MIDI) (22).

Cells of the strain SW451 were Gram-positive coccobacilli with the size of 1.0–1.5 µm (Fig. 3). Colonies on BHI-M agar were ivory yellow, raised and entire edge with 0.2–0.5 cm in diameter. Strain SW451 grew between 37°C and 45°C with optimum growth at 45°C. The optimum pH for the growth was 7, and growth was observed at pH 6–7.5. The strain grew strictly under anaerobic condition, indicating that this strain is an obligate anaerobe. Strain SW451 utilized D-arabitol, D-fructose, L-fucose, D-galacturonic, palatinose, and rhamnose, and exhibited positive detection of alkaline phosphatase, leucine arylamidase, valine arylamidase, acid phosphatase, α-galactosidase, β-galactosidase, and α-glucosidase. Based on the results obtained in Biolog AN microplate and API ZYM, the carbon utilization and enzyme activity of strain SW451 were different from the closely related strains (Table 1). The predominant cellular fatty acids of strain SW451 included C_{16:0} (20.80%), C_{14:0} (17.98%) and C_{16:0} DMA (15.83%) in which differed from the reference strains (Table 2). The overall characteristics of the strain were summarized in Table 3.

Description of *Sellimonas caecigallum* SW451 sp. nov.

Sellimonas caecigallum sp. nov. (referring to L. n. *caecum*, caecum; L. gen. n. *gallum*, of a chicken; N.L. gen. n. *caecigallus*, from the caecum of a chicken). Cells are strictly anaerobic, Gram-stain-positive and non-motile. The average size of each cell is 1.0–1.5 µm and coccobacillus-shaped. Colonies are visible on BHI-M agar after 2 days and are approximately 0.2–0.5 cm in diameter, ivory yellow, raised with entire edge. The strain exhibits optimal growth in BHI-M medium at 45°C and pH 7. The strain utilizes D-arabitol, D-fructose, L-fucose, D-galacturonic, palatinose, and rhamnose as a carbon source. Positive enzymatic reactions are obtained for alkaline phosphatase, leucine

arylamidase, valine arylamidase, acid phosphatase, α -galactosidase, β -galactosidase, and α -glucosidase. The primary cellular fatty acids are C_{16:0}, C_{14:0} and C_{16:0} DMA. The genome of this strain is 2.67 Mbp with 45.13 mol% of G+C content. isolated from the cecum of feral chicken. The type strain is SW451 (DSM 109473^T)

Nucleotide sequence accession number

The 16S rRNA gene and genome sequence were deposited in GenBank and SRA under accession numbers MN053974 and PRJNA551641, respectively.

Deposit in culture collection

Strain SW451 was deposited in the DSMZ culture collection under number DSM109473.

Conflict of interest

None to declare

*Summed features are fatty acids that could not be separated using the MIDI System. Summed feature 1 contains C_{13:1} and/or C_{14:0} aldehyde. Summed feature 13 contains C_{15:0} anteiso and/or C_{14:0} 2-OH; summed feature 8 comprises C_{17:1} ω8c and/or C_{17:2} at 16; summed feature 10 contains C_{18:1} ω7c and/or unknown.

Table 3. Description of strain SW451, according to the digitized protologue

(www.imedeas.uib.es/dprotologue) website

Taxonumber	TA01013
Species name	Sellimonas caecigallum
Genus name	Sellimonas
Species epithet	caecigallum
Species status	sp. nov.
Species etymology	ce.ci.gal'lum N.L. gen. n. referring to the caecum of a chicken where the type strain was isolated.
Designation of the type strain	SW451
Strain collection numbers	DSM 109473
16s Rrna gene accession number	MN053974
Genome accession number	PRJNA551641
Genome size	2.67 Mbp
GC mol%	45.13
Country of origin	United State
Region of origin	Brookings, South Dakota
Source of isolation	caecum of feral chickens
Gram stain	positive
Cell shape	small chain coccobacilli
Cell size	1.0–1.5 µm
Motility	non-motile
Colony morphology	0.2–0.5 cm in diameter, ivory yellow, raised with entire edge
Temperature range	37–45° C
Temperature optimum	45 ° C
pH range for Growth	6–7.5
pH optimum	7
Relationship to O ₂	anaerobe
