14  
15       **Abstract**

16       The past decade has seen the rise of omics data, for the understanding of biological  
17       systems in health and disease. This wealth of data includes protein-protein interaction  
18       (PPI) derived from both low and high-throughput assays, which is curated into multiple  
19       databases that capture the extent of available information from the peer-reviewed  
20       literature. Although these curation efforts are extremely useful, reliably downloading  
21       and integrating PPI data from the variety of available repositories is challenging and  
22       time consuming.

23       We here present a novel user-friendly web-resource called PINOT (Protein Interaction  
24       Network              Online              Tool;              available              at  
25       [http://www.reading.ac.uk/bioinf/PINOT/PINOT\\_form.html](http://www.reading.ac.uk/bioinf/PINOT/PINOT_form.html)) to optimise the collection  
26       and processing of PPI data from the IMEx consortium associated repositories  
27       (members and observers) and from WormBase for constructing, respectively, human  
28       and *C. elegans* PPI networks.

29       Users submit a query containing a list of proteins of interest for which PINOT will mine  
30       PPIs. PPI data is downloaded, merged, quality checked, and confidence scored based  
31       on the number of distinct methods and publications in which each interaction has been  
32       reported. Examples of PINOT applications are provided to highlight the performance,  
33       the ease of use and the potential applications of this tool.

34 PINOT is a tool that allows users to survey the literature, extracting PPI data for a list  
35 of proteins of interest. The comparison with analogous tools showed that PINOT was  
36 able to extract similar numbers of PPIs while incorporating a set of innovative features.  
37 PINOT processes both small and large queries, it downloads PPIs live through  
38 PSICQUIC and it applies quality control filters on the downloaded PPI annotations (i.e.  
39 removing the need of manual inspection by the user). PINOT provides the user with  
40 information on detection methods and publication history for each of the downloaded  
41 interaction data entry and provides results in a table format that can be easily further  
42 customised and/or directly uploaded in a network visualization software.

43

46

## 47 **Background**

48 During the past two decades the use of omics data to understand biological systems  
49 has become an increasingly valued approach (1). This includes extensive efforts to  
50 detect protein-protein interactions (PPIs) on an almost proteome-wide scale (2, 3).  
51 The utility of such data has been greatly supported by primary database curation  
52 and the International Molecular Exchange (IMEx) Consortium, which promotes  
53 collaborative efforts in standardising and maintaining high quality data curation  
54 across the major molecular interaction data repositories (4). The primary databases,  
55 such as IntAct (5) and BioGRID (6), are rich data resources providing a  
56 comprehensive record of published PPI literature. PPI data are critical to describe  
57 connections among proteins, which in turn supports both inference of new functions  
58 for proteins (based on the guilt by association principle (7)) and visualization of  
59 protein connectivity via shared interactors. This support shedding light on communal  
60 pathways involving proteins of interest (8-10). Additionally, literature extracted PPI  
61 data can support the prioritization of interactions from high-throughput experiments  
62 (which generate large lists of potential PPI hits), assisting the selection of candidates  
63 for further analysis/validation (11).

64 However, the process of collating PPI data from multiple sources is currently  
65 hampered by the fact that no single data source encompasses the full extent of PPIs  
66 reported in the literature, requiring users to merge (partial) information mined from  
67 different primary databases. Furthermore, merging such data is not straightforward

68 due to inconsistencies in data format and differences in data curation across the PPI  
69 databases (IMEx members vs non-members).  
70 To optimize the use of PPI data from the public domain, we developed a user-  
71 friendly tool that assists PPI data extraction and processing: the Protein Interaction  
72 Network Online Tool (PINOT). This tool represents the development (and  
73 automation) of our previous PPI analysis framework (i.e. weighted protein-protein  
74 interaction network analysis - WPPINA) (9, 11-15). Through PINOT, PPI data is  
75 downloaded directly (i.e. downloaded “live” at the time of the query) from seven  
76 databases using the Proteomics Standard Initiative Common Query Interface  
77 (PSICQUIC) and integrated to ensure a wide coverage of the PPIs available from  
78 these repositories (16). These data are scored through a simple and transparent  
79 procedure based on ‘method detection’ and ‘publication records’ and allows the user  
80 to further apply customized confidence thresholds. PINOT is fully automated and  
81 available online as an open access resource. Output data are provided as a  
82 summary table (directly online or emailed to the user), which summarizes the most  
83 comprehensive current knowledge of the PPI landscape for the protein(s)-of-interest  
84 submitted in the query list. Of note, the R scripts which underlie PINOT can be freely  
85 downloaded from the help-page.

86

## 87 **Methods**

88 *Protein Interaction Network Online Tool (PINOT)*  
89 PINOT can be run automatically at  
90 [http://www.reading.ac.uk/bioinf/PINOT/PINOT\\_form.html](http://www.reading.ac.uk/bioinf/PINOT/PINOT_form.html) (hereafter referred to as  
91 “webtool”). A choice of parameters is integrated by default as explained further below  
92 and in Supplementary Materials (S1). Alternatively, R scripts can be downloaded from  
93 the help-page (hereafter referred to as “standalone tool”, since parameters can be  
94 modified as per user choice).

95 A list of proteins of interest (seeds) can be queried to identify their literature-reported  
96 interactors that have been curated into PPI databases (Figure 1).

## 101 FIGURE 1 – PINOT user interface

102 A. Screenshot of the PINOT webpage, B. Examples of the text file to be uploaded or list to  
103 be populated into the text box of query seeds (i.e. proteins for which protein interactors will  
104 be extracted from primary databases that manually curate the literature), C. Example result  
105 output file from PINOT, containing the extracted and processed PPI data (only the file's  
106 header is reported as an example), D. Example of the discarded proteins log file from  
107 PINOT, a text file reporting all the seeds for which interactions are not returned to the user,  
108 and E. Example of the network providers log file from PINOT containing a list of active  
109 databases that were utilised for downloading PPI data.

110

111

112 For *Homo sapiens* (taxonomy ID: 9606) the seed identifiers submitted into the query  
113 field must be in an approved HUGO Gene Nomenclature Committee (HGNC) gene  
114 symbol or valid Swiss-Prot UniProt ID format. Upon query submission, PPI data are  
115 extracted directly (via API: Shannon, P. (2018) PSICQUIC R package, DOI:  
116 10.18129/B9.bioc.PSICQUIC (17)) from seven primary databases, all of which directly  
117 annotate PPI data from peer-reviewed literature: bhf-ucl, BioGRID (6), InnateDB (18),  
118 IntAct (5), MBInfo (<https://www.mechanobio.info>), MINT (19) and UniProt (20). The  
119 downloaded protein interaction data are then parsed, merged, filtered and scored  
120 (Figure 2) automatically by PINOT. Detailed description of the PINOT pipeline can be  
121 found in the supplementary materials (S1). The user can select to run PINOT with  
122 lenient or stringent filter parameters. The output of PINOT (Figure 1C-E) consists of:

123 i) a network file (final\_network.txt), which is a tab-spaced text file containing the  
124 processed PPI data in relation to the seeds in the initial query list; ii) a log file  
125 (final\_network\_log.txt) reporting proteins that have been discarded from the initial  
126 query list, and; iii) a log file (final\_network\_providers.txt) indicating the PPI databases  
127 used by the API at download. The output dataset is available for download and/or  
128 emailed to the user.

129 For *Caenorhabditis elegans* (taxonomy ID: 6239) the seed identifiers must be in an  
130 approved WormBase gene ID (21) format, “WBGene” followed by 8 numerical digits.  
131 Upon submission PPI data are downloaded from an internal network stored within  
132 PINOT and created (following similar criteria applied for the human PPIs - details in  
133 S1) based on the WormBase PPI catalogue (Alliance\_molecular\_interactions.tar file  
134 downloaded from the Alliance of Genome Resources on 15th April 2019). The user  
135 can apply stringent or lenient filtering options. The output of PINOT for a *C. elegans*  
136 query consists of: i) a network file (final\_network.txt), which is a tab-spaced text file  
137 containing the processed PPIs for the seeds in the initial query list; and ii) a log file  
138 (final\_network\_log.txt) reporting proteins that have been discarded from the initial  
139 query list.

#### 140 *Software*

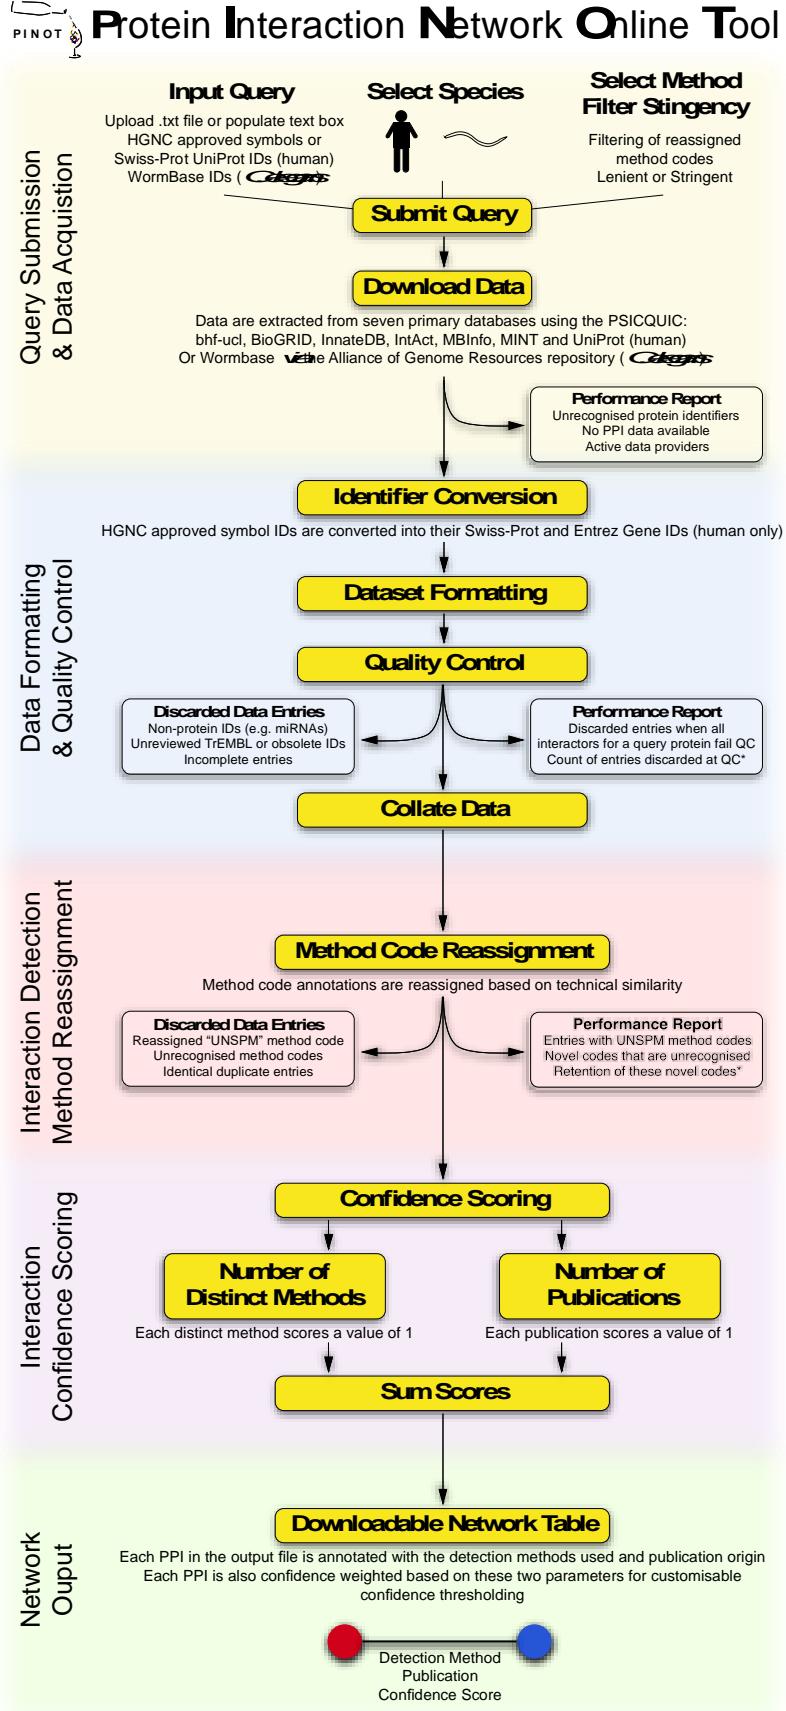

141 The PINOT pipeline is coded in R and runs on a Linux server at the University of  
142 Reading, with java servlets processing user's submissions *via* the web interface.

#### 143 *PINOT quality control*

144 We have tested the PINOT pipeline using multiple input query lists structured as  
145 follows: i) small input lists = 6 sets of 1 to 5 proteins, selected randomly or in  
146 association with typical processes suspected to be functionally relevant for  
147 Parkinson's Disease (PD); and ii) large input list = 941 proteins, the mitochondrial  
148 proteome as reported by MitoCarta2.0 (22).

149 PINOT was compared to two other related online tools. For this analysis, searching  
150 parameters were selected (where possible) to maximize the extraction of protein  
151 interactions: the Human Integrated Protein-Protein Interaction Reference (HIPPIE)  
152 was used with confidence score = 0 and no filters on confidence level, interaction type  
153 or tissue expression; and the Molecular Interaction Search Tool (MIST) was used with  
154 no filtering rank to download only protein protein interactions. Importantly and of note,  
155 files from HIPPIE and MIST required manual parsing after download to remove entries  
156 that were associated to no PMID and/or no conversion method code (incomplete

157 entries). Data were downloaded on 18th September 2019 (*H. sapiens*) and on 24<sup>th</sup>  
158 September 2019 (*C. elegans*).

\*features available when running the pipeline manually

160 **FIGURE 2 – PINOT pipeline**

161 A stepwise insight into the process which underlies the PINOT pipeline. Performance reports  
162 (green boxes) are generated and data are discarded (red boxes) at numerous stages within  
163 the pipeline to ensure high quality and transparent data processing.

164

165 **Results**

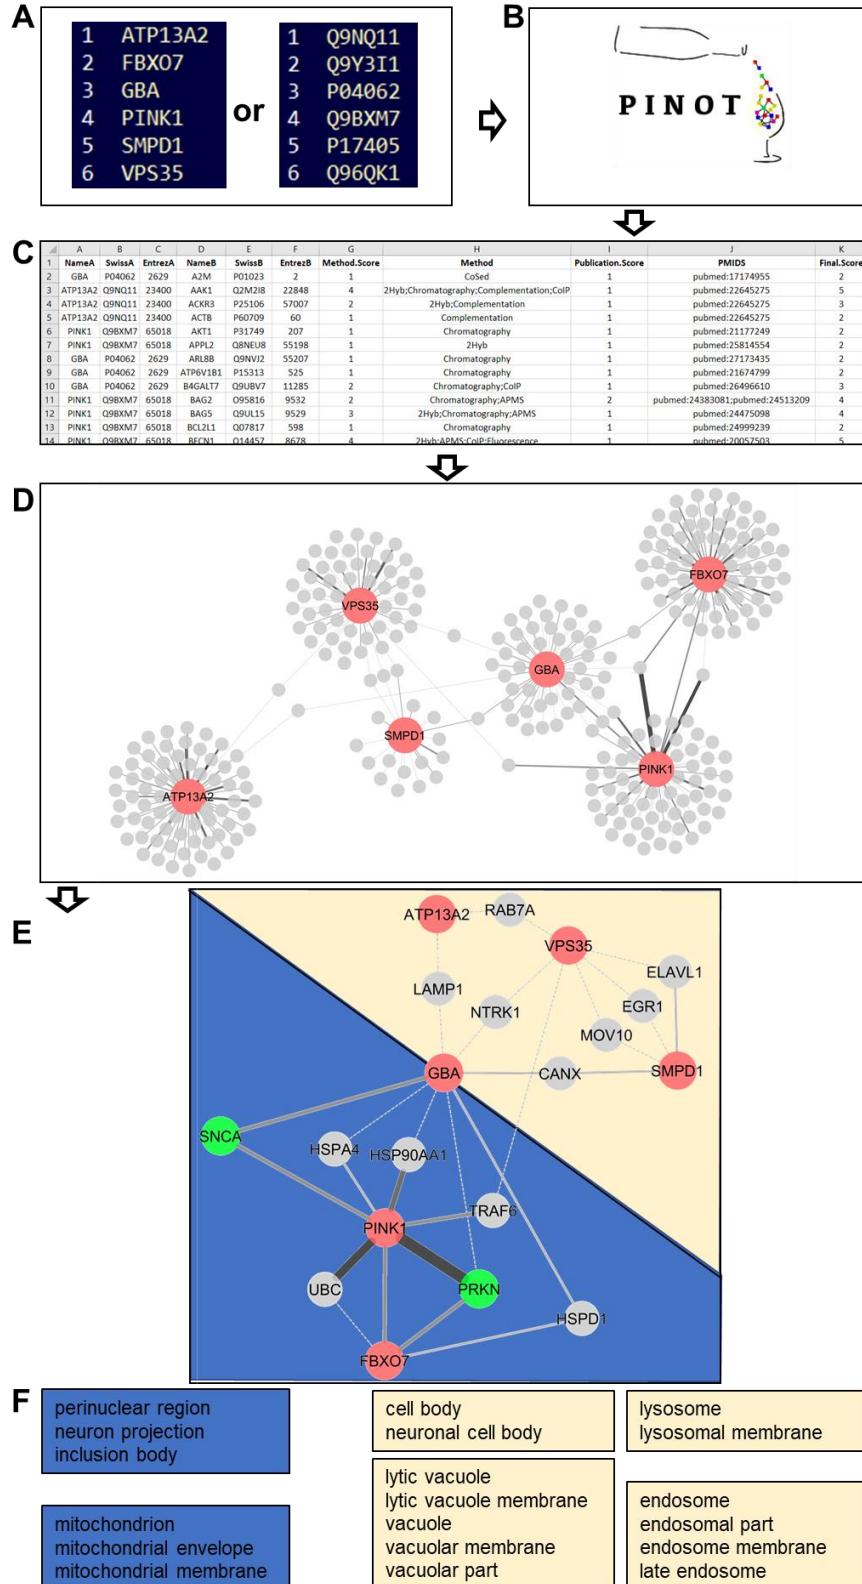

166 PINOT is a webtool that takes a list of proteins/genes (seeds) as input and returns a  
167 table containing a comprehensive list of PPIs - published in peer-reviewed literature –  
168 centred upon the seeds. This table consists of a variable number of rows and 11  
169 columns (Figure 1C and 3C). Each row represents a binary interaction between one  
170 of the seeds (interactor A) and one of its specific protein interactors (interactor B). The  
171 11 columns contain: the gene name, the Swiss-Prot protein ID and the Entrez gene ID  
172 for interactor A and B (“NameA”, “SwissA”, “EntrezA”, “NameB”, “SwissB”, “EntrezB”);  
173 the number and type of different methods through which the interaction has been  
174 identified (“Method.Score”, “Method”); and the number of different publications  
175 reporting the interaction and the corresponding PubMed IDs (“Publication.Score”,  
176 “PMIDS”). The final column (“Final.Score”) contains a confidence score based on the  
177 number of different methods + the number of different publications reporting the  
178 interaction. PPIs with a final score of 2 are reported in literature by 1 publication and  
179 detected by 1 technique; these PPIs are considered “suggestive” (but are clearly not  
180 “replicated”). They might be either: i) false positives, or ii) true novel interactions that  
181 have not yet been replicated in additional studies. A final score >2 suggests a degree  
182 of replication that can be either or both: multiple publications reporting the PPI and  
183 multiple techniques used to detect the interaction. It is not possible to obtain a final  
184 score <2 since every PPI annotation – to be retained in PINOT – has to be supported  
185 by at least 1 interaction detection method and 1 PMID; if this condition is not met, the  
186 PPI is discarded by PINOT and not shown in the output file.

187 The PINOT output can be imported into Cytoscape (23) for network visualization by  
188 selecting the “NameA” and “NameB” columns as source and target nodes,  
189 respectively.

190 *PINOT: Example of application*

191 In Figure 3 PINOT has been used to download PPIs for a limited selection of human  
192 protein products of genes mutated in familial PD: ATP13A2, FBXO7, GBA, PINK1,  
193 SMPD1 and VPS35 (seeds). PINOT quickly retrieved a table containing 327

194 interactions from peer-reviewed literature (with associated PMIDs) thus supporting  
195 and simplifying otherwise time-consuming classical literature mining. The PINOT  
196 output was imported into Cytoscape and PPIs were visualized in a network (“NameA”  
197 = source and “NameB” = target), the seeds were highlighted in dark-red and the edges  
198 (interactions between each protein) were coded based on the “Final.Score” field, thus  
199 highlighting the confidence (number of methods + number of publications) of the  
200 interaction. Since we were interested in interactors that were common to the seeds -  
201 and not in “private” interactors of just one seed - the network was filtered retaining only  
202 the nodes (interactors) that bridged two or more seeds. The obtained core-network  
203 revealed that among the common interactors of the seeds (PD proteins) there were 2  
204 proteins (SNCA and PRKN), which are products of 2 additional genes known for being  
205 mutated in familial PD. Thus, the analysis pointed towards the involvement of SNCA  
206 and PRKN in PD even if they were initially excluded from the list of seeds. Additionally,  
207 topological analysis (based on the number and strength of the edges) suggested the  
208 core network could be subdivided into 2 distinct clusters respectively including PINK1,  
209 FBXO7 and the newly identified PRKN and SNCA in the first cluster, while ATP13A2,  
210 VPS35 and SMPD1 were more closely associated in the second cluster, with GBA a  
211 bridge seed between the 2 clusters. This observation suggested a dichotomy, based  
212 on the protein interactomes, of the seeds included in the initial input list. Based on the  
213 guilt-by-association principle we hypothesised that the proteins contributing to these  
214 clusters could be associated with different cellular functions and components. We  
215 therefore performed functional enrichment analysis (based on Gene Ontology (GO)  
216 Cellular Component (CC) annotations) using g:Profiler (24) revealing that indeed,  
217 clusters 1 and 2 are associated with mitochondria and  
218 vacuoles/lysosomes/endosomes, respectively.

219

220

### 221 Figure 3 – PINOT: An example application

222 A stepwise insight into the potential use of PINOT. 1. A submission list is created as a text file  
 223 using gene names as per HGNC approved symbols or Swiss-Prot IDs; the submission list can  
 224 be uploaded as file or pasted into the PINOT interface. 2. PINOT downloads from PSICQUIC

225 the human PPIs (in this example, stringent filters applied) 3. PPIs are provided back to the  
226 user *via* email or from the webpage; results are in a parsable file that can be opened by a text  
227 reader application and imported into Microsoft Excel. 4. The interactions can be visualized in  
228 a network format by opening the PINOT output through Cytoscape. Connections between  
229 nodes (edges) are coded with increased line width based on the final score that interaction  
230 was assigned by PINOT. The wider the edge – the more confident PINOT is about the  
231 interactions. 5. The interactions can be further processed according to the user's research  
232 question, in this case, only interactors that are communal to at least 2 of the initial query  
233 proteins have been retained, generating a core network (in dark-red the initial seeds; in bright-  
234 green the identified common interactors that are proteins mutated in PD). Based on the  
235 network topology the seeds and their interactors can be visually clustered into group 1  
236 (depicted in gold) and group 2 (depicted in blue). 6. Specific functional enrichment (GO CC  
237 terms) for groups 1 and 2 after filtering out the less represented terms. Analyses performed  
238 on the 22<sup>nd</sup> August 2019.

239

#### 240 *H. sapiens* - PINOT performance

241 The performance of PINOT was compared to that of alternative resources for both  
242 small and large numbers of seeds. Regarding the former, five different small seed lists  
243 were used as input for PPI query in HIPPIE (25) and MIST (26), two alternative online  
244 and freely available resources. It should be noted that, despite apparent similarities,  
245 each of these tools has been developed differently. All three resources (PINOT,  
246 HIPPIE and MIST) have distinguishing features for addressing different research  
247 questions (Table 1). The results of the different queries have been compared,  
248 evaluating the total number of interactors provided in the output (Figure 4A).

249 PINOT, HIPPIE and MIST retrieved a similar number of PPIs. PINOT with stringent  
250 filtering applied, was always extracting fewer interactions; this is an expected outcome  
251 since this filter option is built with the purpose of retaining only annotations that have  
252 survived stringent screening, largely based on completeness of curated data entries.  
253 The large input list was compared in PINOT and HIPPIE, the only two webtools that  
254 allowed for easy processing of more than 900 seeds within the submission list. In fact,  
255 MIST submission needed to be divided into multiple small lists to allow the browser to  
256 properly process the query. Additionally, the downloaded table(s) were not parsable  
257 (in an automated fashion), thus making MIST (the version available at the time of the  
258 query) counterintuitive for the processing of large input lists. The number of retrieved  
259 interactors was slightly higher for HIPPIE in comparison with PINOT when the  
260 stringent QC filter was applied; while PINOT with lenient filtering retrieved more  
261 interactions than HIPPIE (Figure 4B). Additionally, the vast majority of downloaded

262 interactions were similar from using the two resources, suggesting that PINOT is able  
263 to confidently extract specific interactions from literature (Figure 4C).  
264

265

266

#### 267 **Figure 4 – PINOT: Performance & Sensitivity**

268 A. PINOT performance was evaluated by counting the number of interactors retrieved (gene  
269 names) upon submission of the reported query lists to PINOT (with stringent and lenient  
270 filtering), HIPPIE and MIST (on 18th September 2019). The databases were set to retrieve the  
271 maximum number of interactions (by removing all possible filters). The HIPPIE and MIST  
272 outputs were manually cleaned to remove interactions with i) no interaction detection method;  
273 ii) no PMID; iii) multiple Entrez IDs. The number of retained interactions retrieved is reported

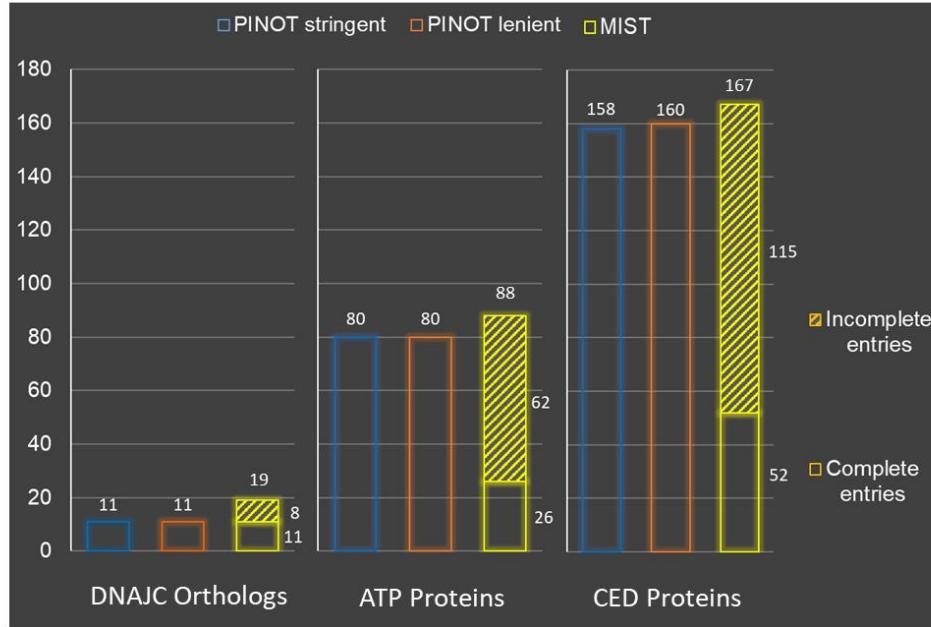

274 on top of each bar. B. PINOT (with stringent and lenient filtering) and HIPPIE were queried to  
275 retrieve PPIs for a seed list of 941 protein from Mitocarta 2.0. C. Comparison between PINOT  
276 and HIPPIE showing that the vast majority of interactors (Entrez IDs) downloaded by the two  
277 tools was identical: 6790 common interactors for PINOT lenient (640 unique interactors) vs  
278 HIPPIE (355 unique interactors); 6572 common interactors for PINOT stringent (319 unique  
279 interactors) vs HIPPIE (573 unique interactors).

280

281 *C. elegans - PINOT performance*

282 The performance of PINOT for querying *C. elegans* PPI data was tested alongside the  
283 *C. elegans* query option in MIST, assessing interaction networks of different  
284 dimensions (Figure 5). The data acquisition strategy underlying these two resources  
285 differs slightly, PINOT extracts data from the latest release of WormBase molecular  
286 interaction data, whereas MIST utilises data from numerous sources, including  
287 WormBase, BioGRID and IMEx associated repositories.

288 Similarly to comparisons across the human PPI query capacity, PINOT and MIST  
289 performed comparably in terms of the number of PPI data entries extracted. More  
290 specifically and as previously described with human data, PINOT extracting slightly  
291 fewer across these test query cases. However, upon assessing the completeness of  
292 these extracted data entries, in terms of interaction detection method and/or PMID  
293 annotations, there was a striking difference in performance. Since the PINOT pipeline  
294 focusses particular emphasis on the QC of data, all data entries within the output  
295 dataset were complete, whereas incomplete data entries persisted in the MIST output  
296 dataset thus requiring manual inspection. In the more abundant PPI data pools, for  
297 example when querying the ATP and CED *C. elegans* proteins, incomplete data  
298 entries accounted for the majority of the output dataset in MIST.

299

300

### 301 **Figure 5 – PINOT and MIST performance comparison for *C. elegans* PPI data**

302 The performance of PINOT (with stringent and lenient filter options) and MIST was assessed  
303 in terms of the number of PPI data entries extracted upon querying different protein lists (on  
304 24th September 2019). The output dataset was evaluated in relation to the number of  
305 complete and incomplete (lacking interaction detection method and/or PubMed ID  
306 annotations) data entries extracted. The query lists were PD-associated DNAJC orthologs:  
307 DNJ-14, DNJ-25, DNJ-27, Y73B6BL.12, K07F5.16, RME-8 and GAKH-1; ATP proteins: ATP-  
308 1, ATP-2, ATP-3, ATP-4, ATP-5 and ATP-6; and CED proteins: CED-1, CED-2, CED-3, CED-  
309 4, CED-5, CED-6, CED-7, CED-8, CED-9, CED-10, CED-11, CED-12 and CED-13. The input  
310 format used for PINOT was the WormBase gene ID, the common gene name (as listed here)  
311 was used for MIST querying and no filter by rank parameter was set.

312

### 313 **Discussion**

314 PINOT can be used as a tool to quickly and effectively survey the literature and  
315 download the most up-to-date PPI data available for a given set of proteins/genes of  
316 interest. This is particularly useful to assist anyone attempting to mine overwhelming  
317 abundant literature targeting certain proteins/genes, in relation identifying reported  
318 PPIs.

319 The PPI data downloaded through PINOT can be used as a reference list (from  
320 literature) for experimental PPI data resulting from high-throughput experiments  
321 (protein microarrays; yeast 2 hybrid screens, etc) helping in prioritisation of

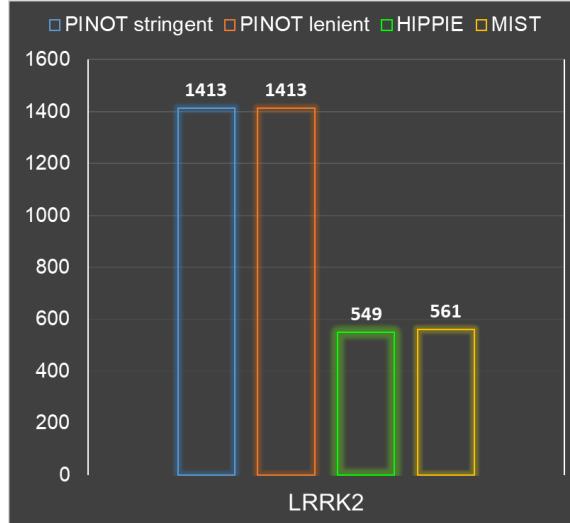

322 experimental results for validation. PINOT can also be useful to evaluate interactors  
323 of different proteins/genes of interest within an input seed list simultaneously. The  
324 analysis of the combined interactomes of such seeds can reveal the existence of  
325 communal interactors, can provide a base to cluster the seeds into groups and can  
326 support further functional analysis to better characterize the functional landscape of  
327 seeds of interest.

328

329 Alternative tools that appear to be similar to PINOT are HIPPIE and MIST. STRING  
330 (27) is a conceptually different tool; it does not report 'interaction detection methods'  
331 nor 'Publication IDs' for PPIs which are crucial pieces of information for the evaluation  
332 and interpretation of PPI data. Additionally, the reported interactions are not focused  
333 only on the proteins in the input list; interactions of interactors are also reported, thus  
334 making it difficult to parse the output table. HIPPIE implements a tailored confidence  
335 score for different methodological approaches; MIST provides a valuable resource for  
336 users interested in mapping PPIs across species (i.e. interologs); PINOT focusses on  
337 high quality PPI data output by implementing multiple QC steps to remove problematic  
338 or non-univocal annotations. PINOT performance was comparable to that of HIPPIE  
339 and MIST both in terms of number and identity of downloaded interactions. However,  
340 there are some unique features of PINOT that are not, at the moment, integrated within  
341 the other databases. Human PPIs in PINOT are directly downloaded from PSICQUIC  
342 at every query submission. In contrast, PPIs in HIPPIE and MIST are recovered from  
343 a central built-in repository within the servers. This difference is clearly demonstrated  
344 by searching for interactors of LRRK2, where (at the time of analysis) 1 high-  
345 throughput publication was updated in PSICQUIC, while both HIPPIE and MIST did  
346 not contain this full annotation yet (Figure 6).

347 PINOT has access to the most up-to-date interactions that could be retrieved at a  
348 given time from PSICQUIC (however, it has to be considered that each database is  
349 responsible for updating their PSICQUIC service and therefore discrepancies might  
350 exist with the central database).

351

## 362 **Figure 6 – LRRK2 interactome**

363 PINOT performance was evaluated by counting the number of interactors retrieved (gene  
364 names) for LRRK2 by using PINOT (with stringent and lenient filtering), HIPPIE and MIST.  
365 The databases have been set to retrieve the maximum number of interactions (by removing  
366 all possible filters). HIPPIE and MIST output were manually cleaned to remove interactions  
367 with i) no interaction detection method; ii) no PMID; iii) multiple Entrez IDs. The number of  
368 the surviving interaction retrieved is reported on top of each bar (18<sup>th</sup> September 2019).

369  
370 PINOT implements QC filtering which involves discarding PPI data entries that are  
371 curated without a PMID and/or the interaction detection method annotation. Therefore  
372 the output file from PINOT does not require any further QC by the user, while lists from  
373 MIST and HIPPIE require manual parsing and inspection before analysis to remove  
374 incomplete data entries through a time consuming, post-hoc processing procedure.  
375 Another distinctive feature of the PINOT pipeline is the implementation of a unique  
376 interaction detection method conversion step. During this step, the interaction  
377 detection method annotation for each downloaded interaction data entry is converted  
378 based on a conversion table (S2) that is available for download from the PINOT web-  
379 portal. During this conversion, technically similar methods are grouped together. For  
380 example: "Two Hybrid - MI:0018", "Two Hybrid Array - MI:0397" and "Two Hybrid  
381 Pooling Approach - MI:0398" are grouped together into the "Two Hybrid" method  
382 category. This step of 'method clustering and reassignment' is critical to assess the  
383 actual number of distinct methods used to describe a particular interaction and to dilute

384 the bias caused in the event of the same technique being annotated under slightly  
385 different method codes in different PPI databases.

386 Interaction scores are provided in different formats for the three tools. HIPPIE  
387 incorporates a filtering system based on a confidence score between 0 and 1 that can  
388 be set either before or after the analysis. This is a complex scoring system, which  
389 takes into consideration multiple parameters, such as the number of publications that  
390 report a specific interaction and a semi-computational quality score based on the  
391 experimental approach (for example, imaging techniques would score less than direct  
392 interactions etc.) (28). MIST similarly has an option for filtering interactions pre- or  
393 post-analysis; however, this is based on fixed ranking values defined as low, medium  
394 (interaction supported by other species), or high (supported by multiple experimental  
395 methods and/or reported in multiple publications). In the case of PINOT, two different  
396 scores are provided: the interaction detection method score (MS) reports the number  
397 of different methods used (after conversion), while the publication score (PS) counts  
398 the number of different publications which report the interaction. Finally, *H. sapiens*  
399 PINOT coding scripts are fully available for download. They are coded in R to make  
400 them accessible to a large research audience; additionally a read me text file helps  
401 customization of the scripts according to the users' needs. Some of the divergent  
402 features across PINOT, HIPPIE, MIST and STRING are reported in Table 1.

403

	PINOT	HIPPIE	MIST	STRING
Live PPI data	yes	no	no	no
Large Submission	yes	yes	no	no
Parsable Table	yes	yes	no	yes
PPIs for seeds only	yes	yes	yes	no
Visualization app	no	yes	yes	yes
Other Species PPIs	yes	no	yes	yes
Score	yes	yes	yes	yes
Pubmed ID (PMID)	yes	yes	yes	no
Detection Method	yes	yes	yes	no
QC on method and PMID	yes	no	no	-
Entrez ID	yes	yes	yes	no
Swiss-Prot ID	yes	no	no	no

Codes available	yes	no	no	no
-----------------	-----	----	----	----

410

411 **List of Abbreviations**

412 HIPPIE = Human Integrated Protein-Protein Interaction Reference; MIST =  
413 Molecular Interaction Search Tool; MS = method score; PPI = protein protein  
414 interaction; PD = Parkinson's Disease; PINOT = protein interaction network online  
415 tool; PMID = Pubmed ID; PS = publication score; PSICQUIC = Proteomics Standard  
416 Initiative Common Query Interface; QC = Quality Control; WPPINA = weighted  
417 protein-protein interaction network analysis.

418

419 **Availability of data:** This resource is available as a fully automated web-server at:  
420 [http://www.reading.ac.uk/bioinf/PINOT/PINOT\\_form.html](http://www.reading.ac.uk/bioinf/PINOT/PINOT_form.html); R scripts, which underlie  
421 this bioinformatics pipeline, are free for download at the help-page.

422 **Competing Interests:** The authors declare that they have no competing interests

423 **Funding:** This work was supported by Biotechnology and Biological Sciences  
424 Research Council CASE studentship with BC Platforms [grant number  
425 BB/M017222/1]; Engineering and Physical Sciences Research Council [grant  
426 number EP/M508123/1]; the Medical Research Council [grant numbers  
427 MR/N026004/1; MR/L010933/1 to JH and PAL]; Parkinson's UK to PAL [grant  
428 number F1002]; Alzheimer's Society to RF [grant number 284]; Alzheimer Research  
429 UK to RCL [grant number ARUK-NAS2017A-1]; the National Institute for Health  
430 Research University College London Hospitals Biomedical Research.

431 **Author's Contribution:** TEJ, MC and FR, elaborated the pipeline and wrote the  
432 manuscript; TEJ, MC and VN wrote the scripts and tested the pipeline, MJL  
433 implemented the pipeline for the website, HJ, LCR, LAP offered critical advice for the  
434 implementation of the pipeline, critically reviewed the manuscript and obtained  
435 financial support.

436 **Acknowledgements:** We thank WormBase for providing the list of PPIs used for  
437 the generation of the internal *C. elegans* network used when *C. elegans*  
438 genes/proteins are queried by PINOT users.
