14

15 Short title: Compensatory mutant in SIV Nef

16 **Abstract**

17 The H₁₉₆ residue in SIVmac239 Nef is conserved across nearly all HIV and SIV isolates,
18 lies immediately adjacent to the AP-2 (adaptor protein 2) interacting domain (ExxxLM₁₉₅),
19 and is critical for several described AP-2 dependent Nef functions, including the
20 downregulation of tetherin (BST-2/CD317). Surprisingly, many stocks of the closely
21 related SIVmac251 swarm virus harbor a *nef* allele encoding a Q₁₉₆, which is associated
22 with loss of multiple AP-2 dependent functions in SIVmac239. Publicly available
23 sequences for SIVmac251 stocks were mined for variants linked to Q₁₉₆ that might
24 compensate for functional defects associated with this mutation. Variants were
25 engineered into the SIVmac239 parental plasmid and mutant viruses were used to test
26 tetherin downregulatory capacity in primary CD4 T cells using flow cytometry.
27 SIVmac251 stocks that encode a Q₁₉₆ residue in Nef uniformly also encode an upstream
28 R₁₉₁ residue. We show that R₁₉₁ restores the ability of Nef to downregulate tetherin in the
29 presence of Q₁₉₆. However, a published report showed Q₁₉₆ commonly evolves to H₁₉₆ in
30 vivo, suggesting a fitness cost. R₁₉₁ may represent compensatory evolution to restore
31 the ability to downregulate tetherin lost in viruses harboring Q₁₉₆.

33 **Introduction**

34 The lentiviral Nef protein is a common target of CD8-T lymphocyte (CD8TL)
35 responses in both HIV-1 infected persons and SIV infected rhesus macaques and
36 readily evolves to evade these responses [1-6]. Nef is highly pleiotropic and mediates
37 the downregulation of several cell surface molecules involved in innate and adaptive
38 immune responses against virus infected cells such as TCR-CD3 (in most SIVs but not
39 HIV-1) [7], CD4 [8-10], CD8 $\alpha\beta$ [11], CD28 [12], tetherin (BST2 or CD317; in most SIVs
40 and in HIV-1 group O, but not HIV-1 group M) [13-15], MHC-I [16], MHC-II [17], CD1d
41 [18], CD80/CD86 [19] and likely others as well as enhancing viral infectivity by
42 preventing virion incorporation of host serine incorporator 3 (SERINC3) and SERINC5
43 proteins [20-23]. Nef-mediated modulation of several of these molecules, including CD4,
44 CD8 $\alpha\beta$, CD28, tetherin, and SERINC3 and SERINC5 requires interactions between Nef
45 and adaptor protein (AP)-2 complexes [11, 20, 24-28].

46 We used high throughput next generation sequencing to track evolution in SIV
47 Nef [29, 30], with particular focus on viral escape from antiviral CD8TL responses,
48 including CD8TL targeting the SIV Nef IW9 (IRYPKTGW₁₇₃, with subscript numbers
49 representing the position in the SIVmac239 Nef protein) and MW9 (MHPAQTSQW₂₀₃,
50 hereafter referred to as MW9) epitopes in rhesus macaques that express Mamu-
51 B*017:01. MW9 overlaps the well-defined “di-leucine” ExxxLM₁₉₅ motif and lies
52 immediately upstream of the DD₂₀₅ di-acidic motif also important for AP-2 binding [31].
53 Though selection eventually favored changes of the first position in MW9, specifically
54 M₁₉₅I or M₁₉₅V, an H₁₉₆Q (second position in MW9) substitution was initially favored in
55 several animals. Since this variant was never fixed and generally lost soon after arising,
56 we hypothesized it may have represented an effective escape mutation yet imparted a
57 negative impact on Nef function. Specifically, we tested whether functions involving

58 interactions with AP-2 would most likely be impacted, given the close proximity of this
59 epitope with the ExxxLM₁₉₅ AP-2 interaction domain. Not surprisingly, the H₁₉₆Q variant
60 selectively disrupted Nef functions that rely on interactions with AP-2, such as
61 downregulation of tetherin, CD4, and CD28 and disrupted Nef's ability to reduce
62 SERINC5-mediated reductions of viral infectivity, while having no impact on MHC-I or
63 CD3 downregulation, functions that do not rely on AP-2 interactions [32, 33]. In that
64 study, we did not identify any potential compensatory mutations that allowed for regain
65 of function in the presence of the H₁₉₆Q variant leading to this variant being only
66 fleetingly detected and eventually replaced by escape mutations with less significant
67 impacts on important Nef functions.

68 Many isolates of SIVmac251, a commonly used strain in SIV studies, harbor a
69 Q₁₉₆ in the viral Nef protein. In this study, we sought mutations linked to Q₁₉₆ that might
70 compensate for loss of function associated with this residue. We then used publicly
71 available viral sequences to determine if Q₁₉₆ was stable in vivo. We identified an
72 upstream variant, R₁₉₁ (E₁₉₁ in SIVmac239) that compensates for the loss of tetherin
73 downregulation associated with Q₁₉₆. However, we also found that Q₁₉₆ routinely mutated
74 to H₁₉₆ in vivo, suggesting reduced fitness despite the maintenance of tetherin
75 downregulation associated with the combination of Q₁₉₆ and R₁₉₁ residues.

76

77 **Materials and Methods**

78 ***Ethics Statement.*** Cells used in this study were taken from blood from six Indian-origin
79 rhesus macaques (*Macaca mulatta*) that are part of the breeding colony at the Tulane
80 National Primate Research Center. Animals were anesthetized as part of their routine
81 semi-annual health assessment (SAHA) and additional blood was drawn for this study.
82 Thus, animals were not anesthetized specifically for the studies described herein. All
83 animals were housed in compliance with the NRC Guide for the Care and Use of

84 Laboratory Animals and the Animal Welfare Act. Blood draws were approved by the
85 Institutional Animal Care and Use Committee of Tulane University (OLAW assurance
86 #A4499-01) under protocol P0191. The Tulane National Primate Research Center
87 (TNPRC) is fully accredited by AAALAC International [Association for the Assessment
88 and Accreditation of Laboratory Animal Care(AAALAC#000594)], Animal Welfare
89 Assurance No. A3180-01. Breeding colony animals at the TNPRC are housed outdoors
90 in social groups and frequently monitored by veterinarians and behavioral scientists. The
91 animals were fed commercially prepared monkey chow and supplemental foods were
92 provided in the form of fruit, vegetables, and foraging treats as part of the TNPRC
93 environmental enrichment program. Water was available at all times through an
94 automatic watering system. The TNPRC environmental enrichment program is reviewed
95 and approved by the IACUC semiannually. Veterinarians at the TNPRC Division of
96 Veterinary Medicine have established procedures to minimize pain and distress through
97 several means. Monkeys were anesthetized with ketamine-HCl (10 mg/kg) or
98 tiletamine/zolazepam (6 mg/kg) prior to all procedures. The above listed anesthetics
99 were used in accordance with the recommendations of the Weatherall Report.

100
101 Primary cell isolation, culture and infection. Primary CD4 T cells were magnetically
102 isolated from PBMC from healthy rhesus macaques using nonhuman primate CD4
103 microbeads (Miltenyi) according to the manufacturer's protocol. Isolated cells were
104 stimulated with concanavalin A for two days and cultured thereafter with R15/50 media,
105 comprised of RPMI media with 15% FBS and 50U/ml IL-2. SIV infections were
106 conducted using the spinoculation technique [34] with each 1ml aliquot of virus
107 (approximately 10⁸ viral RNA copies per milliliter) layered on 100ul of 20% sucrose
108 solution and centrifuged for 1 hour at 4°C at 20,000xg. After removal of the supernatant,
109 the concentrated virus was resuspended in 100ul of R15/50 media and gently dripped

110 onto one million CD4 T cells plated at 1 million cells/ml in 48 well plates. Plates were
111 then spun at 2000rpm for 2 hours at room temperature. After centrifugation, plates were
112 placed in 37C humidified incubators with 5% CO₂. Cells were cultured for 36 hours
113 before harvest for flow cytometry assays.

114

115 ***Mutant virus production.*** Mutants of the SIVmac239 virus were generated using site
116 directed mutagenesis of the SIVmac239 3' hemiplasmid, using mutagenesis primers
117 designed using web-based software (PrimerX from bioinformatics.org). To generate the
118 H₁₉₆Q mutation alone, we used the following mutagenesis primers using the QuikChange
119 II Site-Directed Mutagenesis Kit (Agilent); F: GCA TTA TTT AAT GCA GCC AGC TCA
120 AAC TTC CC, and R: GGG AAG TTT GAG CTG GCT GCA TTA AAT AAT GC and to
121 generate the E₁₉₁R mutation on the backbone that already contained the H₁₉₆Q variant,
122 we used the following mutagenesis primers; F: GGC ACA GGA GGA TGA GAG GCA
123 TTA TTT AAT GCA GC, and R: GCT GCA TTA AAT AAT GCC TCT CAT CCT CCT
124 GTG CC. After mutagenesis, plasmids were treated with DpnI to remove non-mutated
125 parental plasmids and cloned into Stbl2 cells (Life Technologies) using the
126 manufacturer's protocol. Mutations were sequence-verified, and successfully mutated
127 plasmids were used for follow-up studies. Mutated 3' plasmids were ligated with the 5'
128 hemiplasmid, transfected into Vero cells followed by harvest of the virus-containing
129 supernatant. Of note, the Nef region of interest overlaps with the 3' long terminal repeat
130 (LTR). Attempts to mutate the full-length SIV plasmid resulted in mutations in both the 5'
131 and 3' LTR regions, which rendered the viruses replication incompetent, necessitating
132 the need for mutating only the 3' hemiplasmid followed by ligation to the wild type 5'
133 plasmid. Some viruses were further expanded in CEMx174 cells. Viral RNA was
134 extracted from all viral stocks and sequenced to ensure the presence of desired
135 mutations.

136

137 *Flow cytometry.* Thirty-six hours after infection, primary cells were stained with labeled
138 antibodies to CD4 (BV421, clone L200, BD Biosciences) and tetherin (PE, clone RS38E,
139 Biolegend), followed by fixation, permeabilization, and intracellular labeling with a FITC
140 labeled antibody against the Gag p27 protein (clone 55-2F12). Data was acquired on a
141 BD LSRII instrument and analyzed using Flowjo v10 software.

142

143 *Structural analysis.* Structures showing interactions between SIVsm Nef, Tetherin, and
144 AP-2 subunits were recently published [35]. We used UCSF Chimera software [36] to
145 probe potential interactions between our Nef residues of interest at positions 191 and
146 196 and host AP-2 and tetherin proteins. The Rotamers function in UCSF Chimera was
147 used to predict impacts of mutations and the Matchmaker function was used to assess
148 positioning of Nef amino acids in SIV relative to HIV-1.

149

150 *Sequence analysis and alignments.* Nef sequences from a broad array of SIV isolates
151 were identified from a published report [37] and downloaded from NCBI for amino acid
152 alignments using Geneious Prime 2019.1.3 using the built-in Geneious Alignment
153 algorithm with default settings. SIVmac251 sequences available from published reports
154 [38, 39] were downloaded from NCBI into Geneious Prime 2019.1.3 and mapped to
155 SIVmac239, used as the reference genome, followed by identification and quantification
156 of variations using the Find Variations/SNPs function. Sequences published in the
157 Lamers et al report [39], were first divided into those extracted from the inoculum and
158 from individual tissues, which were analyzed separately.

159

160 **Results**

161 *Conservation of the Nef H₁₉₆ residue among primate lentiviruses.* To assess
162 conservation of the H₁₉₆ residue, we performed alignments of the flexible loop region of
163 Nef from a diverse array of SIV isolates from Africa. Although the flexible loop is, in
164 general, far more variable than the core, we found the H₁₉₆ residue to be almost
165 completely conserved among all isolates sequenced to date (Figure 1A), even more
166 conserved than important residues in the adjacent “di-leucine” ExxxLM₁₉₅ motif, E₁₉₀ and
167 L₁₉₄.

168

169 **Figure 1. Assessment of the conservation of residue 196 in SIV Nef.** Alignment of
170 the Nef core and flexible loop from several strains of SIV (A). Sequences were derived
171 from a recent study [37]. The ExxxLM AP-2 binding motif is boxed and the H₁₉₆ residue
172 (based on SIVmac239 numbering) is highlighted and noted by the arrow. SIVmac251
173 stock sequences from a published study [38] show a variant amino acid upstream of Q₁₉₆
174 (R₁₉₁) that was always associated with Q₁₉₆ (B). Alignments were performed using
175 Geneious Prime 2019.1.3.

176

177 We next scanned publicly available sequences from a recent study that used
178 single genome amplification to extensively examine SIVmac251 challenge stocks [38]. In
179 this report, a Q₁₉₆ residue was detected in a large fraction of sequences from
180 SIVmac251 stock viruses from several labs. Interestingly, there was a perfect linkage
181 between the Q₁₉₆ residue and an upstream R₁₉₁ residue, which is E₁₉₁ in SIVmac239
182 (Figure 1B). Of 38 total sequences that contained the region of interest, derived from
183 three different challenge stocks, 25 sequences contained both R₁₉₁ and Q₁₉₆ while Q₁₉₆
184 was never found in the absence of R₁₉₁. Other nearby variants relative to SIVmac239
185 were detected but only R₁₉₁ co-occurred with Q₁₉₆ in all sequences.

186

187 Upstream compensatory variant restores tetherin downregulation. Given the strong
188 linkage between the R₁₉₁ (E₁₉₁ in SIVmac239) variant and Q₁₉₆, we tested whether R₁₉₁
189 allowed tetherin downregulation in the presence of Q₁₉₆. The R₁₉₁ residue lies within the
190 ExxxLM₁₉₅ motif (EEHYLM₁₉₅ in SIVmac239, ERHYLM₁₉₅ in many SIVmac251 isolates).
191 We introduced the E₁₉₁R variant along with the H₁₉₆Q onto the SIVmac239 backbone to
192 assess tetherin downregulation. Viruses harboring H₁₉₆Q alone were largely deficient in
193 tetherin downregulation, as expected. When E₁₉₁R was introduced along with H₁₉₆Q, the
194 resulting virus showed full competency in tetherin downregulation, similar to SIVmac239
195 (Figure 2A). N-fold analysis of tetherin downregulation in cells from multiple animals
196 demonstrated significant loss of downregulation in the virus harboring only H₁₉₆Q, while
197 the addition of E₁₉₁R restored this ability to wild type levels (Figure 2B).

198
199 **Figure 2. SIVmac251 maintains tetherin downregulation despite a unique AP-2**
200 **binding motif.** (a) Representative flow cytometric analysis of surface expression of
201 tetherin on primary CD4 T cells infected with wild type SIVmac239 or SIVmac239
202 harboring the H₁₉₆Q variant alone or in combination with the E₁₉₁R variant. Cells were
203 identified as infected via intracellular Gag p27 staining, top row, as we have described
204 previously [29, 30]. Infected cells (p27+) are orange, while uninfected (p27-) are blue.
205 Surface expression of tetherin compared between infected cells (orange line) and
206 uninfected (blue line) are shown in the bottom panels. (b) N-fold analysis of tetherin
207 downregulation from multiple experiments using cells derived from at least three different
208 RM and compared by way of a two-tailed t-test.

209
210 Structural insights. The structure of SIVsm Nef bound to simian AP-2 was recently
211 published [35]. We used UCSF Chimera structural analysis software [36] to assess how
212 the residues at positions 191 and 196 interact with host AP-2 and tetherin molecules.

213 The critical residues in the dileucine motif [E₁₉₀, L₁₉₄, V₁₉₅ (M₁₉₅ in SIVmac239)] show
214 clear interaction with AP-2, while H₁₉₆ is oriented in the opposite direction (Figure 3A),
215 similar to H₁₆₆ in HIV-1 (Figure 3B) [28], which is homologous to H₁₉₆ in SIV. We next
216 used the Rotamers function in UCSF Chimera to determine whether the H₁₉₆Q variant
217 impacted interactions with AP-2. Replacement of the H with a Q at this position resulted
218 in a large number of possible rotamers for Q₁₉₁, nearly all of which maintained a similar
219 orientation as H₁₉₁, directed away from AP-2, suggesting no obvious impact on the
220 interaction between Nef and AP-2. However, the H₁₉₆Q variant is predicted to disrupt a
221 salt bridge between H₁₉₆ and tetherin residue D₁₅ as assessed using PISA (Proteins,
222 Interfaces, Structures, and Assemblies) software [40], suggesting disruption of a direct
223 interaction between Nef and tetherin may contribute to the selective disadvantage of this
224 change.

225

226 **Figure 3. Structural insights into Nef, AP-2, and tetherin interactions.** (a) Although
227 adjacent to the ExxxLM motif that directly binds Nef to AP-2, H196 is oriented away from
228 this interaction. (b) Alignment between SIVsm and HIV-1 Nef (PDB: 4NEE) with H₁₆₆
229 (HIV-1) and H₁₉₆ (SIVsm) highlighted. (c) T₁₉₁ in SIVsm directly interacts with K₁₈ in the
230 DIWK motif of tetherin.

231

232 Position 191 is a T in SIVsm, as opposed to E₁₉₁ in SIVmac239. While this residue does
233 not contact AP-2, intriguingly, it does interact directly with the K₁₈ residue in the DIWK
234 motif of the tetherin protein itself via a hydrogen bond (Figure 3C). Replacement of T₁₉₁
235 with an E (as in SIVmac239) maintained the predicted hydrogen bond with K₁₈,
236 suggesting this interaction holds true between SIVmac239 and tetherin. Further,
237 replacement of E₁₉₁ with an R resulted in only low probability orientations, preventing a
238 meaningful analysis of this structural change.

239

240 *In vivo stability of the Q₁₉₆ residue.* Finally, we wished to assess the in vivo stability of
241 the Q₁₉₆ residue. We hypothesized that since the combination of Q₁₉₆ and R₁₉₁ residues
242 allowed for efficient tetherin downregulation in vitro, that Q₁₉₆ would be stable in vivo
243 when it exists in combination with R₁₉₁. We used publicly available sequences from a
244 recent study wherein macaques were infected with an stock of SIVmac251 that harbored
245 virus with nearly 90% containing the combination of Q₁₉₆ and R₁₉₁ [39] based on our
246 analysis of their deposited sequences. That study used a modified Single Genome
247 Amplification (SGA) method to quantify viral variation in plasma throughout infection and
248 multiple neurological tissues at necropsy. After infection, the Q₁₉₆ residue was detectable
249 primarily at three weeks post infection, with the exception of a small number of reads
250 that contained Q₁₉₆ at 3 months. This residue was thereafter lost in all three animals and
251 was not detected in any neurological sites in any animals at necropsy (meninges,
252 parietal lobe, temporal cortex) (data available in the cited manuscript and in their
253 deposited sequences).

254

255 **Discussion**

256 The SIVmac251 viral swarm is pathogenic in rhesus macaques and has been
257 used in hundreds of studies to date. However, this swarm has been independently
258 grown in many labs using multiple cell types and under a variety of conditions [38]. It
259 stands to reason that there may be genetic differences between SIVmac251 viral stocks
260 leading to unique biological differences, but few of these differences have been
261 characterized for how they impact specific virologic properties, including the
262 downregulation of host tetherin.

263 The ability to downregulate host tetherin is a feature of a wide variety of
264 enveloped viruses ranging from Ebola to HIV [41, 42]. Most SIV isolates use the viral Nef

265 protein to perform this task [13, 43, 44] but several isolates use alternate pathways,
266 suggesting strong selection to maintain this function. Surprisingly, Nef encoded by
267 SIVcpz cannot downregulate human tetherin and studies suggest that evolution of HIV-1
268 Vpu to gain the ability to downregulate tetherin was a critical event in the HIV-1 epidemic
269 [43, 45]. Thus, countering tetherin likely is an important feature of all or nearly all SIV
270 and HIV isolates.

271 In addition to interactions with host AP-2 proteins, SIV Nef is known to interact
272 directly with the tetherin protein [46] and a subset of those interactions were recently
273 verified structurally [35]. These structures show that H₁₉₆ does not directly interact with
274 host AP-2 but is predicted to form a salt bridge with tetherin, which is predicted to be
275 disrupted in the H₁₉₆Q variant using PISA software [40]. However, our previous report
276 showed that the H₁₉₆Q variant disrupted multiple Nef functions that rely on AP-2
277 interactions suggesting that disruption of a direct interaction with tetherin likely does not
278 fully explain the functional deficits identified in this variant. Here, we show that evolution
279 of the E₁₉₁R variant restored tetherin downregulation in the presence of Q₁₉₆. Intriguingly,
280 T₁₉₁ in SIVsm interacts directly with the lysine in the DIWK motif in the tetherin protein
281 [35], suggesting variation at this residue may impact tetherin downregulation via a direct
282 effect on this interaction. E₁₉₁ in SIVmac may also interact with this K₁₈ residue as these
283 two amino acids are well known to form hydrogen bonds, although we cannot confirm
284 without structural data.

285 Many strains of SIVmac251 encode a Nef protein with a Q₁₉₆ residue, which is
286 always linked to an upstream R₁₉₁ residue. Here we show that the presence of R₁₉₁ fully
287 restores competency in downregulation of tetherin in the presence of Q₁₉₆. Nonetheless,
288 our data also suggest that Q₁₉₆ is not stable in vivo and evolves to H₁₉₆, the residue
289 present in nearly all SIV isolates. These data beg the question of how the Q₁₉₆ residue
290 arose in the first place. It's possible it arose during replication in cultured cells where

291 selection pressures are undoubtedly different than those the virus experiences in vivo.
292 Given our data suggesting the H₁₉₆Q variant can arise in vivo in SIVmac239 infected
293 macaques as a result of escape from CD8TL responses [30], these data may suggest
294 that SIVmac251 was isolated from an animal that targeted this region with CD8TL,
295 leading to viral escape, and prior to other escape variants becoming dominant, as
296 happened in our previous study [30].

297 Taken together, our mutational and functional data combined with published
298 structural and sequence data suggest the possibility that the E₁₉₁R variant in SIVmac
299 might enhance an interaction between Nef and tetherin thus restoring the ability of Nef to
300 downregulate tetherin in the presence of the H₁₉₆Q variant, but that this variant may not
301 restore other functions, thus leading to selection to restore H₁₉₆ in vivo. The existence of
302 compensatory variation in viral proteins has been described in SIV and HIV-1 [47-50] but
303 those descriptions are restricted to viral structural proteins, primarily Gag. Our data
304 suggest R₁₉₁ in SIVmac251 may exist to compensate for loss of function associated with
305 Q₁₉₆. If so, this may be the first report of compensatory variation in the viral Nef protein
306 or any nonstructural viral protein. However, our analysis of published in vivo data clearly
307 demonstrate that Q₁₉₆ evolves to H₁₉₆ in vivo. Finally, our data do not suggest that stocks
308 of SIVmac251 that harbor a Q₁₉₆ residue are in any way less useful than stocks that do
309 not. Instead, our data underscore the need to understand the evolutionary pressures that
310 give rise to particular viral variants, which may be relevant in the choice of virus stock for
311 animal model experiments.

312

313 **Author contributions**

314 NJM conceived the study and wrote the first draft. BS conducted the experiments and
315 edited all drafts.
